This summary of the quantitative studies of Professor Bickel and his students is an amplification of a public address recently delivered, and consequently the conclusions and interpretations are given without the evidence on which they are based, which may be found in part in more technical publications. Some of them, at variance with previous observations, require further analysis and experimental verification before they can be unqualifiedly accepted. They are briefly as follows: 1. Alcohol frequently, but not regularly, has a specific dynamic effect, increasing the total metabolic rate. 2. The rate of oxidation of the alcohol itself is increased by small doses but diminished by large amounts of alcohol. 3. The presence of alcohol hastens the oxidation of other materials in the body. 4. Alcohol burns faster during muscular work but does not itself serve as a source of muscular power. 5. The effect of alcohol on the blood sugar or on the sugar tolerance curve is not consistent. 6. The normal insulin supply of the body controls the height of the blood sugar without definite effect on the blood alcohol content. 7. The injection of insulin subcutaneously produced a lowering in the alcohol content of the blood, in addition to the reduction in the blood sugar. The lowering of the blood alcohol through insulin is greater with larger doses of insulin and with lower blood sugar levels. 8. With high blood sugar and high blood alcohol concentrations, insulin causes a lowering of the blood sugar without influencing the blood alcohol concentration but may cause a shortening of the intoxication by insulin "blockade" of the ganglion cells. 9. The height of the blood alcohol content therefore is within certain limits no infallible index of the amount of the total disturbance of the nervous system at a particular moment. 10. The insulin treatment of alcoholic intoxication in man may serve as a therapeutic possibility for the consideration of the clinician. The observations discussed are both theoretically stimulating and clinically attractive. Before the classic dictum of Mellanby that the rate of oxidation of alcohol in the body is independent of concentration or external factors is abandoned, however, further work is necessary to demonstrate that the results reported may not in fact be explainable on the basis of variable excretion rather than oxidation rates and that the differences observed are really statistically significant. It is to be hoped that Professor Bickel and his students will continue their investigations and that other workers may confirm their results before the therapeutic suggestions made are given uncorroborated clinical application.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Editors: H. Letheby, Tidy, M.A. M.D. F.R.C.P., and A. Rendle Short, M.D. B.S. B.Sc. Fifty-fourth year, 1935. Cloth. Price \$6. Pp. 555 with 154 illustrations. Baltimore: William Wood & Company [n.d.].

This book has established itself as a classic. It is the work of leading authorities and the fifty-fourth year of publication is a sufficient testimony to its merit. The editors wisely say in the introduction that "a year book must record the proceedings of the previous year like the minutes of a meeting. Minutes contain no implication that the opinions expressed by the speakers are justified or that the conclusions arrived at are correct." The introduction contains a short review of the principal accomplishments of 1935 in various fields of medicine. The scope of the book is not limited to internal medicine but includes also surgery, obstetrics, gynecology, radiology and related subjects. Such diversified themes as diets for athletes, school medical service and industrial diseases have not been overlooked. The handy book is illustrated with numerous charts, photographs, reproductions of roentgenograms, photomicrographs and colored plates. The usefulness of this work cannot be questioned, it should be helpful to the practitioner who desires concise and accurate information concerning recent advances in medicine. An impression gained from a brief review of the book is that the last year offered an unusually large number of comparatively simple new therapeutic methods for a great diversity of ailments. The arrangement of subjects in alphabetical order is open to criticism, as overlapping can not be avoided in many instances. The editors rendered a distinguished service, particularly to those who for some reason or other cannot avail themselves of library facilities.

The Treatment of Asthma. By F. T. Harrington, M.R.C.S. L.D.S.P. Cloth. Price 6s. Pp. 112 with 3 illustrations. London: H. K. Lewis & Co. Ltd., 1935.

This small book is published under the ambitious title of the treatment of asthma. With the exception of the first few chapters it is essentially a concise discussion of the general dietary and hygienic aspects of asthma. The author's rationalizations and theories on the etiology and pathogenesis of asthma will find little general acceptance. His idea that "without toxemia we cannot have asthma and treatment which does not include some means of lessening the toxic load is futile" would have been more convincing if he had been more explicit about the toxin or the mechanism by which it acts. That proper food and alimentation is important in the management of asthma will be readily agreed on but that these are fundamental factors will be seriously questioned. It is unfortunate that many of the author's practical statements are obscured by some of his poorly grounded theories. Had the author been content with dealing with diet and hygiene in asthma he would probably have provided the profession with a concise, usable text book. There is little else in this work to recommend it to the physician.

Recent Advances in Dermatology. By W. Noel Goldsmith, M.A. M.D. M.R.C.P. Physician to St. John's Hospital for Diseases of the Skin. With foreword by A. M. H. Gray, C.B.E. M.D. F.R.C.P. Cloth. Price \$5. Pp. 522 with 58 illustrations. Philadelphia: P. Blakiston's Son & Co. Inc., 1935.

This is an unusually able summary of the advances in dermatologic knowledge during the last twenty years. The author has emphasized particularly the newer research in immunology and biochemistry as related to cutaneous disorders and gives an impartial presentation of the views of different observers along with a personal commentary. The material is presented in an orderly fashion beginning with a consideration of such fundamental subjects as the blood vessels and glands of the skin and pigmentations. Of particular value are the chapters on the reticulo-endothelial system, disorders of metabolism, allergy, tuberculosis, fungous infections, filter passing virus, cancer and radiant energy. Each chapter is well illustrated and accompanied by a pertinent bibliography. To the practical dermatologist this digest of an enormous amount of research material should be of great value in the scientific study of diseases, although it emphasizes more the increasing complexity of modern dermatology.

MEDICOLEGAL ABSTRACTS

Accident Insurance Death from Preexisting Heart Disease Aggravated by Strain.—The insurance company promised to pay certain benefits if the insured died from 'personal bodily injury effected directly and independently of all other causes through accidental means, and which injury causes total and continuous inability to engage in any kind of business or labor' The insured died from heart failure following overexertion. He had a preexisting heart condition described in the record as a "chronic valvular condition that had lasted so long that the valves had become calcified" The cause of death, as stated in the death certificate, was 'aortic mitral insufficiency present since childhood,' and the contributing cause was given as "acute cardiac dilation induced by overexertion in hauling a boat out of water" In a suit to recover the benefits, the trial court gave judgment for the beneficiary and the insurance company appealed to the Supreme Court of Wisconsin.

That the insured suffered a heart injury while pulling up the boat was undisputed. Assuming the death to have been caused by accidental means, the court said, the question arises as to whether the overexertion can be considered as having caused the death "independently of all other causes" If a disease or bodily condition exists and an accident occurs, to constitute the accidental means the sole cause of an injury it is sufficient if the accidental means would have solely caused some considerable injury had the disease or bodily condition not existed. If no considerable injury would have resulted had the insured not been afflicted with the existing disease or condition, the accidental means cannot be considered as the sole cause of the injury. From the undisputed evidence in the present case, no considerable injury would have occurred in the absence of the preexisting heart condition. The heart condition must therefore be considered as a substantial factor in causing the death. The death was not attributable, concluded the court, solely to accidental means within the meaning of the policy and the judgment of the circuit court for the beneficiary was reversed, with directions to dismiss the complaint.—*Herthel v Time Ins Co (Wis)* 265 N W 575

Workmen's Compensation Acts Pneumothorax Attributed to a Strain.—The employee, Delaune, while assisting in lifting a press cover weighing about 300 pounds, experienced a sharp pain in the region of his left lung. The following morning, while on his way to work, pneumothorax developed. Attributing this development to the strain of the preceding day, Delaune sought compensation under the workmen's compensation act of Louisiana. From a judgment awarding compensation, the employer appealed to the court of appeal, Orleans.

Two expert witnesses, on behalf of the employee testified that the collapse of the employee's lung was due to the strain which reawakened a dormant tuberculosis. One witness for the employer, on the other hand testified that the effort in lifting the press cover could not have caused the lung to collapse except by a very remote possibility. He testified that a person's lung may collapse without any exertion at all and that, in his opinion, tuberculosis was the sole cause in the present case. If the collapse of the lung had been caused by the exertion, this witness testified, it would have been a total collapse and the employee would not have been able to continue work until the end of his shift as he did. Another expert witness, appearing for the employer testified that the strain was too remote, in time from the collapse of the lung to have been its cause and that a person whose lung collapses by reason of injury or trauma would be unable to continue work. After reviewing this testimony, the court was of the opinion that the testimony for the employee must prevail over the testimony of the experts for the employer who while expressing the opinion that the strain did not produce the pneumothorax, con-

ceded that it might have done so. The judgment awarding compensation was therefore affirmed, subject to an amendment with respect to the number of weeks during which compensation must be paid.—*Delaune v Young (La)*, 166 So 149

Malpractice Mistake in Identity of Physician.—An operation was performed on Mrs McDonald Nov 23, 1930, for the removal of her appendix and fallopian tubes. Three years later a second operation was necessitated and a piece of gauze was found in her abdominal cavity. Peritonitis developed and the patient died. Attributing the death to the presence of the sponge, which, it was contended, was negligently left in the abdominal cavity after the first operation, suit was instituted against the defendant, Dr Garnier, alleging that he performed the first operation. The trial court gave judgment for the defendant and the plaintiffs appealed to the court of appeal of Louisiana, second circuit.

The testimony as to who performed the first operation was both conflicting and, to say the least, most unusual. Mrs McDonald was, according to evidence, a patient of Dr J N Jones, a surgeon, who testified that he did his own surgical work. Neither the patient nor her husband ever had a consultation with Dr Garnier. There was no request made that he operate, and he never submitted a bill for the operation. Witnesses for the plaintiff, consisting of Dr Jones and five relatives of the deceased, all testified that Dr Garnier performed the operation. Against this testimony, however, a physician who assisted in giving the anesthetic and the nurse who assisted in the performance of the operation both testified unequivocally that Dr Garnier was not present during the operation and that it was performed by Dr Jones. Furthermore, the evidence was convincing that Dr Garnier was in a different city at the time the operation was performed and could not physically have participated in it. A preponderance of the evidence, in the opinion of the court, was in favor of the defendant. The judgment of the lower court for the defendant was therefore affirmed.—*McDonald v Garnier (La)*, 166 So 147

AMERICAN ASSOCIATION FOR THE STUDY AND CONTROL OF RHEUMATIC DISEASES

*Third Annual Meeting and Fifth Conference on Rheumatic Diseases
held in Kansas City Mo May 11 1936*

LORING S SWAIN, MD, Secretary

(Concluded from page 458)

The Differential Diagnosis of Rheumatic Fever

DR. R. A. KINSELLA, St Louis The approach to the differential diagnosis of rheumatic fever must begin with a clear recognition of the disease itself. The various features that make up the so-called rheumatic state are in themselves insufficient for diagnosis and may exist in combination even in those conditions which are not rheumatic fever.

There are two features which seem to distinguish the disease in a definite way. The first of these is the rather short duration of the reaction about a given joint, even while the disease continues in other joints. This period of sojourn is usually from three to five days, during which symptoms and signs are definite, although stiffness and indefinite soreness may persist for a longer time. The second and most important feature is cardiac involvement.

Cardiac involvement endows vague symptoms, such as "growing pains" with definite value. Without cardiac involvement, no single feature or combination of features in the so-called rheumatic state makes the diagnosis. With this idea accepted, differentiation from Still's disease, rheumatoid arthritis, gonorrheal rheumatism and bacterial arthritis is possible.

From Still's disease, rheumatic fever differs in many ways, although in the beginning of Still's disease the features may be similar. Acute rheumatic fever in children is usually accompanied by a devastating form of cardiac involvement which is entirely absent in Still's disease. In the latter disease the involvement of joints is tenacious and progressive, leading to permanent deformity, while in rheumatic fever the involvement of joints leads to no structural changes that are lasting.

Early cases of atrophic (rheumatoid) arthritis in young adults may closely imitate the clinical display of rheumatic fever. This is especially true in those cases in which there is fever, and tender red areas about joints, which last only a few days in each location. There is, however, a definite preference for small joints, the course is prolonged and leads eventually to permanent structural deformities, and throughout the prolonged course the heart remains intact. In both Still's disease and atrophic (rheumatoid) arthritis, which many regard as the same disease, subcutaneous nodules occur—a feature that is found also in rheumatic fever.

DISCUSSION

DR. T. DUCKETT JONES, Boston Because the age groups of rheumatic fever subjects coincides with that of so-called Still's disease, these two offer the greatest difficulty in differential diagnosis. The typical cases of each disease need not be confused but also it must not be overlooked that the two occur simultaneously. While the latter is not common it is not unusual to see a child with definite heart disease of the rheumatic fever type and active carditis in progress who also shows definite and progressive joint change characteristic of Still's disease. There are two types of Still's disease which offer difficulty. Occasionally one sees children with fever and severe joint pain, swelling and no evident heart disease and the patient recovers and is seemingly well. After varying periods there may be recurrences of this episode and the process continues with this story for several years prior to the development of permanent or appreciable joint change. I know of no diagnostic methods that are proof positive of either rheumatic fever or Still's disease in this group and the diagnosis must rest on the ultimate course of the disease process. A further type of Still's disease offering difficulty in diagnosis is the rare patient with pericarditis early in the course of acute illness. In some such cases evident slight enlargement or hypertrophy of the heart has been observed for a period of several years without evidence of valvular disease and the subsequent course does not seem to be similar to cases of heart disease as a result of

rheumatic fever. In postadolescents and young adults the difficulty of differentiating between rheumatoid arthritis and rheumatic fever may be impossible. Typical cases of either may be easily differentiated, as Dr. Kinsella has noted. Here again the two diseases may occur simultaneously. Transient changes demonstrated by electrocardiogram may show the presence of an active heart lesion, while examination of the joints may show progressive permanent joint damage. Cases of acute polyarthritis in this age group often may be indistinguishable from rheumatic fever and the diagnosis definitely determined only after a long period of observation. Salicylate therapy has not seemed to be of great diagnostic aid. Whether or not rheumatoid arthritis and rheumatic fever are in any way etiologically connected has been a subject for discussion for years and I see no way in which it can be settled at present. While the characteristic life story of the two diseases varies—one showing heart damage and the other progressive joint damage, there are points of similarity which make one wonder whether they may not be to some degree related. However, I have not seen any appreciable instances of rheumatoid arthritis develop in a large group of rheumatic fever subjects followed for a number of years. The suggestion that the variation between the two diseases is dependent on age, that there are strong similarities between the histologic picture of the nodules noted in the two, that both have chronic and recurring courses, as well as the fact that there are certain bacteriologic and immunologic factors which seem to play a part in each, leaves the question of a close etiologic connection muddled. I feel that cases in which there is a suggestion of both diseases should be carefully studied and that this possible relationship will be settled only when the agent of one or the other disease is known and it will be possible to have specific tests. I would make a plea that this society maintain its interest in rheumatic fever. In recent years rheumatic fever has been shown to be a disease with pathologic changes throughout the body, and while death is usually the result of damage to the heart, there are many other important general factors and it would be unwise to investigate the disease purely from a cardiology point of view. If physicians will keep open minds and observe large numbers of patients with rheumatoid arthritis and rheumatic fever it may be possible ultimately to solve many of the problems concerning the two separately, and the question of a common etiologic factor.

DR. RALPH H. BOOTS, New York Dr. Kinsella introduced a group of cases about which little has been said. These cases are occasionally referred to as "focal infection arthritis," not uncommon in older persons, sometimes suspected of being due to infected prostates. This seems to be an entity quite distinct from rheumatoid arthritis. Regarding the frequency of rheumatoid arthritis in older persons, although most patients are affected before 40 years of age, many of these continue with the disease the remainder of their lives, which accounts for its frequency in older persons. The patient referred to by Dr. Snyder was a woman, so the prostate was not a factor.

Differential Diagnosis of Traumatic Arthritis

DR. WILLIS C. CAMPBELL, Memphis, Tenn Little interest has been shown in this class of joint disorders "low grade traumatic arthritis." The etiology is trauma causing organic changes in the articular structures repeated occupational trauma, overuse or faulty posture with unequal articular pressure. The discussion is confined to the knee joint.

The changes after trauma depend on the intensity of the trauma and the reaction of the individual. The irritating process may involve the synovia, capsule or cartilage. Fluid may occur. Fibrinous adhesions may follow. The villi increase. Beneath the synovia the fibrous tissue reaction may impair circulation, giving a dusky hue to the synovia. Cartilaginous masses of embryonic cells are formed as loose bodies, osteochondritis or synovial osteochondromas. Fibrillation of the articular cartilage causes rough areas over the surface. Osteoporosis of the knee extremities follows every toxic or traumatic irritation. It is a characteristic mottling of the cavernous extremities. In hypertrophic changes are induced and osteophytes along the margins of the articulation occur. The pathologic process differs in that granulations, tuberculosis, round cell infiltration and infection are absent. The symptoms of pure trauma

arthritis may be pain, swelling or effusion again it may appear perfectly normal. Crepitation of a thickened capsule or villi or friction fremitus, as in pleurisy, may be present. There is no heat. Motion may not be limited. The history of immediate symptoms following trauma in the absence of other factors may determine the diagnosis. Only in those under 30 can one be fairly certain that a process is entirely traumatic.

Traumatic arthritis in which trauma is a factor but associated with other clinical and pathologic entities forms the largest group in which trauma plays a practical role. Such patients are approaching middle age. Hypertrophic arthritis is frequently the complicating agent. Trauma may induce persistent symptoms when hypertrophic changes are present in the spine. The question between trauma and previously existing disease arises in medicolegal work. "Uncomplicated traumatic arthritis exists only as a definite clinical entity in the young, male athletes most commonly. The pathology is definite. When other affections as hypertrophic arthritis, gout, syphilis, tuberculosis are present and trauma occurs, as careful a differential diagnosis is required as if no trauma had occurred. Biopsy may be the only way to be sure."

DISCUSSION

DR. CHARLES L. LOWMAN, Los Angeles. One thinks of traumatic arthritis as local or remote, with reactive changes in the immediate region of injury, in or near a joint, or in one or more adjacent or remote joints to which the jar or stress has been transmitted at the time of injury. Changes may occur in the spine when the major trauma is in the legs or pelvis or may be in the shoulder, the result of a fall on the hand injuring the wrist area. Traumatic arthritis is characterized by capsular thickening, irritation of synovial fringes, contusions, cracks or compression reaction in articular cartilages, interference with function, pain, tenderness, muscle atrophy, swelling, and often crepitation. Roentgenograms often show cartilage changes, spurring or lipping, and increased density of joint margins at the area of injury with adjacent atrophy not shown on the opposite side. At later stages an osteoporosis below the lesion may also be shown, which may be just adjacent to the joint or may involve a more extensive area, for instance, the whole wrist and hand when the lesion is in the elbow or shoulder, or the whole foot after leg fracture or a sprained ankle. In a young person, definite relation to specific trauma without arthritis in other localities is a great help in diagnosis, yet the coexistence of arthritis in other locations is no criterion of the nonexistence of a real traumatic arthritis. In compensation cases especially beyond the age of 40 the degree of static stress with incident moderate chronic arthritis, or the presence of definite rheumatoid or osteo-arthritic changes, makes it difficult to judge the worker's status and compensability. I feel that one is justified in giving the benefit of the doubt to the worker if he has been continuously employed and has given continuous service until interrupted by the injury. Dr. Campbell correctly points out that osteoporosis is probably due to a sympathetic nerve upset, which may occur especially in the presence of constitutional tendencies, such as glandular imbalance. Its occurrence with traumatic arthritis greatly prolongs the convalescence, giving a sensitive painful member which may be made worse by careless or improper handling. One must not be confused as to acuity of symptoms when the patient may have had faulty physical therapy, such as the improper use of heat either too deep or too prolonged. Pain and spasm are reduced by heat and the patient feels a sense of relief but many use the faulty technique of following it with active movement. The heat congests the area involved, enlarging the fringes. Unless they are drained and lessened in size by elevation and by depleting massage movement will pinch and irritate the joint constituents enough to produce more swelling and tenderness resulting in continuing spasm. Thus the ignorant may produce the very condition they are trying to remedy. One should not only make a diagnosis of the specific lesion but continue to diagnose the status at various intervals. When a technician reports that limitation of motion at a given point has not changed for two weeks new roentgenograms should be taken, diagnosis of the new status made and treatment

altered. If physicians will keep in mind the picture Dr. Campbell has shown of what is occurring in the traumatized joint, they will not go wrong in treatment, and much time and cost will be saved for all concerned.

Differential Diagnosis of Tuberculous Arthritis

DR. FRANK D. DICKSON, Kansas City, Mo. Tuberculous arthritis produces 20 per cent of the handicapped children in this country. It has a high mortality rate estimated as 20 per cent. There are three types.

1 Monarticular, the most usual and accepted type. Diagnostic criteria depend on the stage of involvement. There are two stages: an early stage without radiologically visible osseous foci and a later stage with definite changes. Early diagnosis is important because cure (if ever) is possible with function. Local objective signs and the laboratory examinations, negative Pirquet and Mantoux tests and positive guinea-pig inoculation are trustworthy. There is no characteristic x-ray picture. Later, with chronic joint involvement, and remissions, biopsy and x-ray examinations show uniform thinning of the cortex of the bone, destruction or thinning of the articular cartilages, decalcification of the bone ends, lack of new bone formation, presence of foci of bone destruction (epiphyses) and failure of the destructive process to extend along the shaft of the bone but tending to involve the neighboring joint.

2 Multiple tuberculous arthritis. The tuberculous process occurs in several joints in from 3 to 13 per cent of the cases. There is usually an interval in the involvement more than three intervals is unusual and against tuberculous arthritis.

3 Tuberculous polyarthritis. Poncet in 1897 described the so-called tuberculous rheumatism. The two forms were acute and subacute polyarthritis resembling rheumatic fever, and a chronic form resembling atrophic and hypertrophic polyarthritis. This type is rarely recognized and the literature is unconvincing. Kubirschky's six diagnostic points are refractoriness to salicylates, no endocarditis, presence of other tuberculous disease, positive tuberculin tests, positive animal inoculation from synovial fluid and predominance of mononuclear cells in the synovial fluid. So far there is little proof of the existence of this type of arthritis. Diagnosis of tuberculous joint disease is based on the history, local evidence and laboratory observations. Roentgenograms are of value only in the later stage.

DISCUSSION

DR. J. ALBERT KEY, St. Louis. Chronic progressive monarticular arthritis in the child is considered tuberculous arthritis until it is proved otherwise. I have never been concerned about the early diagnosis of tuberculous arthritis. I do not think it matters whether a tuberculous joint is diagnosed this month, next month or next year, and the reason is this: In this country I have not seen a single instance in which a large weight-bearing joint that was tuberculous was cured with useful motion. I am concerned not with the early diagnosis but with the positive diagnosis. Just as soon as I am sure that the joint is tuberculous I make it my purpose to eliminate that joint by arthrodesis. That is the only way I know by which the patient can be cured of tuberculosis. If a good bony ankylosis is obtained he is cured. If it isn't, the patient has a tuberculous joint as long as he lives. There are two ways of making the diagnosis in the early stage. One is aspiration and injection into a guinea-pig. I think Dr. Dickson is right about subcutaneous inoculation. I have always used intraperitoneal injection and I have had two negative guinea pigs from a joint which later was proved to be tuberculous. The other is biopsy. I have looked at many synovial membranes and when I find a typical tubercle I think it is tuberculosis. When I do not find typical tubercles I do not know. To treat the case expectantly is hard because most of these cases are in children and the parents want the child cured. If it is tuberculosis, the next thing to do is to pick a time to operate on the child or adult. The most important thing in the diagnosis of tuberculosis is the differentiation of a tuberculous joint from a pyogenic joint, strange as it may seem. If one operates on a fulminating tuberculous joint and tries to do an arthrodesis, one is apt to get into trouble. I have done it twice and both patients died, one before amputation and one after. There can

be all gradations in a tuberculous joint, from a simple synovitis with practically no thickening of the synovial membrane and negative x-ray signs which may persist over a period of years to a fulminating joint that is hot and exquisitely sensitive. The usual type is the one that is moderately sensitive with a doughy feel, a thickened synovial membrane, and not much fluid in the joint. I have performed synovectomy on two occasions for rheumatoid arthritis and when the sections came through I found it was tuberculosis. The symptoms recurred in a few months and an arthrodesis was done. On another occasion I drained an acutely involved elbow for a presumably pyogenic infection and the sections showed tuberculosis. The tuberculous rheumatism of Poncet as I recall it, is a tuberculosis without tubercle bacilli and without tubercles. I have never seen a case. I do not think it exists. I think Poncet was a man who was seeing rheumatoid arthritis but was so hipped on tuberculosis that he called his rheumatoid arthritis tuberculous arthritis.

DR. EDWIN W. RYERSON, Chicago. Yesterday I saw in Billings Hospital of the University of Chicago with Dr. Phemister a woman of 50 odd years, with typical severe, old arthritic manifestations, which are so familiar. Her hands, elbows and knees were swollen. She had been that way for years. A few weeks ago both elbows developed swelling just above the joint. Phemister cut into both of these and proved that they were tuberculous. After investigation they found a tuberculous process in the neck. I have seen two cases of pneumococcal arthritis in the joint, one in a child and the other in a woman. After evidently being proved pneumococcal, they ran a prolonged course and were later found to be tuberculous without tuberculosis in any other portion of the body. Dr. Dickson's paper is timely, because all of us are faced by joints which appear to be arthritic and are later proved to be tuberculous. The converse is also true.

DR. FRANK D. DICKSON, Kansas City, Mo. Five years ago I would not have said what I did. The experience of years has caused me to hold different opinions from those I have held in the past. For example, I have had under my care three cases of synovial tuberculosis of the knee, fairly well proved and cured with function. One of these patients—a boy—rowed on the Princeton crew several years ago, which would indicate a functioning knee. I had the patient under observation from the time he was a young boy, moreover, during the course of his disease he was seen by other surgeons and the diagnosis of tuberculosis was confirmed. Girdlestone reports a recent series of early cases of tuberculosis and recovery with function. These cases were carefully diagnosed. Girdlestone believes from his experience that better results in early cases of joint tuberculosis are not being obtained because they are not being recognized early enough and are not kept at rest long enough. It is my conviction that there has been a small but definite percentage of tuberculous joints in which the diagnoses were made early and recovery has occurred with function. If a tuberculous joint is seen in a child 2 or 3 years of age, one is not going to fuse that joint, it must be treated conservatively until such a time as one can do a fusion successfully. With this method, healing with function may be secured once in a while.

Differential Diagnosis of Gonococcal Arthritis

DR. STAFFORD L. WARREN, Rochester, N. Y. Gonococcal arthritis differs in the main from the large group of arthritides classified as infectious arthritis only in that the etiologic agent is known and can be identified in suitable cases. There is one major clinical syndrome which is of diagnostic importance aside from the discovery of the gonococci and that is the rapidity with which the acute process and the atrophy of the bone and muscle and tendon structures progress.

The diagnosis is made on a history of exposure followed by a yellowish discharge from three to twenty days later accompanied by the sequelae of painful urination and other conditions. Involvement of the prostate or tubal structures may follow the onset of this discharge by a few days or weeks or months and coincidental with this or at some later date any

joint or group of joints may develop symptoms of acute disease. A carefully taken history usually reveals transitory involvement of many joints at the onset over a period of several days followed by the acute major involvement of one or several joints or nearby structures. It is not unusual for the process to flare up successively in other joints. It is not infrequent for the major damage to involve a joint traumatized previously to infection.

Examination shows a bluish red, hot, tender joint not very different in appearance from that due to a nonspecific joint except that it produces unusually severe symptoms. The process may, however, be restricted in some cases entirely to the tendon sheaths or bursae around the joint or to the muscle and fascia near by. The atrophy progresses rapidly from the onset. The discharge from the genital urinary tract may show positive smears in about 40 per cent and positive cultures in about 60 per cent of all suspects, although in these acute cases the smear and cultures are usually positive. Joint, bursa and tendon sheath cultures in the early acute stages yield a growth of gonococci in 80 per cent. Later the joint fluid is sterile. Complement fixation tests on the blood are negative for from two to six weeks. When the patient has recovered, a complement fixation test may become negative within six to eight months, although some may still be positive four years after recovery. Skin tests are still in the experimental stage but may be significant if that material is freshly made. The toxin of the gonococcus produces an erythematous reaction in the skin in the absence of the disease.

In the absence of a history of exposure and negative smears and cultures, the positive blood complement fixation test is probably a significant aid in the diagnosis. I suggest making this test on the joint or bursa fluid also, although any body fluid is probably positive in active cases. With a previous history of infectious arthritis and a recent gonococcal infection with flare up of a joint, the situation is very complicated. A nongonorrheal arthritis may flare up because of the intoxication arising from the gonococcal infection without gonococcal invasion in the joint. Joints damaged probably offer fruitful soil for the gonococci. The acuteness of the reaction and the rapidity with which the joint surfaces are damaged and the rapid onset of the atrophy, far out of proportion to the changes that usually accompany ordinary arthritis, are suggestive points in differential diagnosis. The diagnosis of course cannot be established clearly without the cultivation of gonococci from the joint or synovial fluid.

The manner in which the cultures are made is of vital diagnostic importance. In women cultures should be taken from the discharge from the cervix during the last two days of and the two days following the cessation of the catamenia. In males without discharge after careful prostatic or urethral gland massage, the urethra should be washed out with sterile saline solution, cultures of which should be taken.

The radiographic appearance of diffuse atrophy and the tremendous extent of the bone destruction, considering the short duration of the disease, is characteristic. Chronic cases show extreme deformity and capsular thickening, not commonly found in the case of infectious arthritis. When a growth of the gonococcus is not obtained from the joint fluid and in the absence of a good history of gonococcal infection, the patient should be investigated for brucellosis, tuberculosis, typhoid, syphilis (secondary) and low grade staphylococcal and streptococcal infections. On failure to demonstrate any of these the diagnosis by exclusion is probably infectious arthritis (nongonorrheal).

The fallopian tubes may be sealed off and act as foci for years in the absence of evidence of disease in the lower part of the birth canal. The complement fixation test is of assistance. Chronic prostatitis with an occasional yellowish discharge or bleeding after urination may be due to a small residue of gonococci. Old infected structures and glands in the urethra of both sexes and Bartholin's glands may act as foci. Secondary invaders left as residual foci may help in setting up the syndrome of nongonococcal infection of the genital urinary tract. Such secondary invaders may persist for years.

The febrile reaction is mild in gonococcal infections but the pallor and intoxication and prostration are excessive. Electrocardiographic changes (prolonged PR interval up to 0.21 second) occur in about 5 per cent of all cases. These subside later and are probably due to the gonotoxin. The extreme dysfunction of the quiescent joint may be due in part to the destruction of its surface but in general is due more to the inflexible connective tissue granuloma infiltrating the capsule and other structures surrounding the joints, bursae, tendons and muscles concerned.

DISCUSSION

DR. C. B. FRANCISCO, Kansas City, Mo. I tell medical students that gonorrheal arthritis is one thing about which they need to know the clinical symptoms and story, for the reason that no matter how carefully the laboratory work is done there is a large percentage of cases that cannot be proved by laboratory methods the first time. I use that to illustrate the point that clinical medicine is ordinarily apt to be sufficient. The examination and a positive history or the finding of the gonococcus is positive proof, but it is very difficult to get a proper history. The clinical symptoms are characteristic. The extreme pain without much prostration and without much loss of weight is characteristic when preceded by this floating type of joint involvement. The pain is severe and it is extreme, and yet these patients do not lose a lot of weight. The appetite is good and they do not have much fever. The most important point in diagnosis is to think about it. One never diagnoses a thing that one does not think about, no matter how trivial the case may be.

DR. J. ALBERT KEY, St. Louis. Gonorrheal arthritis usually begins as an acute arthritis, but not always. A chronic low grade synovitis is seen which is not very painful and is due to gonorrhea, also the group is seen which I am trying to separate out at the present time, chronic polyarthritis which is due to the gonococcus but clinically rheumatoid arthritis. Most cases of gonorrheal arthritis are cured by fever therapy. If a patient with arthritis of unknown etiology is put in a cabinet, the temperature raised to 106 or 107 F. for four or five hours and he gets well, that is good evidence that the case was one of gonorrheal arthritis. I think that in the future I shall submit certain patients to fever therapy as a diagnostic procedure and if the arthritis is due to the gonococcus the patient will be cured by the test.

DR. MAURICE F. LAUTMAN, Hot Springs National Park, Ark. Dr. Warren has correctly stressed the ease with which the acute type of gonorrheal arthritis can be diagnosed. However, the differential diagnosis between gonorrheal arthritis and ordinary atrophy or rheumatoid arthritis is at times quite difficult, particularly if nongonorrheal foci of infection are present. In the zeal for eradicating the obvious infective foci, the possibility of a concomitant, postgonorrheal infection is frequently overlooked. Examination of the prostate and prostatic secretion has given a great deal of information. The cultural evidence is usually negative, particularly if the arthritis occurs long after the original infection. There are more or less typical subacute cases of gonorrheal arthritis in which the prostatic smears are negative bacteriologically. In these cases the only observation to which any importance can be attached is the presence of pus cells in the prostatic secretion, particularly by examining the fresh secretion under the high power field. The finding of ten or twelve cells per high power field is enough to incriminate the prostate as a focus of infection, but the finding of gonococcus either in stained specimens or in cultures is necessary to establish definitely a gonococcus foundation for the arthritic condition.

DR. STAFFORD L. WARREN, Rochester, N. Y. First I should like to answer Dr. Key that fever therapy is not a diagnostic procedure. What can be done with infection by known strains of gonococci that will stand forty hours of heating at 41.5 C. and not be cured? About the prostate, I meant to infer that secondary invaders may be left, that the gonorrhea may be gone and yet the prostate be the focus of infection. I think that some of these patients under ordinary conditions still harbor gonococci, and one can demonstrate them if a con-

certed search is carried on, especially if dyes are used to identify one or two colonies, which might be missed on a plate, because the plate is crowded with streptococci and staphylococci.

The Diagnosis of Gout and Gouty Arthritis

DR. PHILIP S. HENCH, Rochester, Minn. The diagnosis of gout is often missed. The conservative view is so prevalent that gout is called rheumatic fever and atrophic, hypertrophic or traumatic arthritis. In a hundred cases of gout an average period of fifteen years had elapsed from the first attack of gouty arthritis to the first diagnosis of gout. Gout is not properly understood. Several hundred cases of typical tophaceous gout and similar cases of pretophaceous gout were studied. Gout and gouty arthritis are not synonymous. There is more to gout than the joint symptoms. The first attack, usually after 40, is sudden, lasting from three to seven days, and completely disappears. Any joint may be affected. A year or two later the second attack lasts from seven to fourteen days. The tempo and severity increase, attacks coming every few months. From monarticular they become polyarticular. The diagnostic point of value is the complete recovery from the individual attacks. From five to forty years (average twelve) after the first attack a change occurs, joints no longer recover, the condition becomes chronic. This is the second stage of attacks and remissions. Finally exacerbations cease, the joints are painless, and the extremities are misshapen with tophi.

Tophi are the one pathologic criterion of gout. The hyperuricemia is first acute and transient, then chronic. It becomes more obvious later even between attacks and finally is always present. Tophi are rare in the first attacks in phase 1, are more common in phase 2, and are constant in period 2. Periarthritic fistulas occur as in tuberculosis. The urate crystals must be removed and examined, because the tophi resemble subcutaneous fibrous nodules of fibrositis and atrophic arthritis. Bone is often replaced by urate deposits. Similar areas are seen in atrophic and hypertrophic arthritis and are therefore not pathognomonic of gout. When the characteristic features (podagra, hyperuricemia, tophi, erosion) are present the diagnosis is highly probable. If the pattern is distinctive for gout in onset, recovery, recurrent attacks, even without tophi, the diagnosis is almost assured. It is not like other arthritis, which is chronic from the start without remissions.

Rheumatic fever, intermittent hydrops, periarthritic fibrositis, psoriatic arthritis, arthritis with ulcerative colitis or hemophilia, and recurrent subdeltoid bursitis, each has distinctive features from gout, although they have remissions.

If the first attack has no pattern, certain things are suggestive, as sex, age, season of the year, speed of onset and development, severity of the pain, joints involved, appearance of the joints, site of tenderness, duration and recovery. Certain renal lesions in mature cases are of diagnostic value. Ninety-eight per cent of patients are males. Gout is rare before 35 years but is the commonest form of acute arthritis among men over 40 and should be first thought of if gonorrhea and acute trauma are excluded. The attacks are mostly in spring and fall and between 2 and 7 a. m. The onset is rapid and reaches a maximum in two days. The pain is excruciating. The area is hot and bluish red, not clammy, cold and bluish white as in atrophic arthritis.

Trauma, dietary indiscretions, exposure, postoperative days, liver therapy, ketogenic diets, salyrgan, ergotamine tartrate or insulin may start acute attacks of gout. This is not true of atrophic arthritis.

Gout involves extra articular and intra-articular tissues, hence tendinitis and olecranon bursitis are almost diagnostic of gout as opposed to atrophic or hypertrophic arthritis. Visceral gout is not proved except in the kidney, where urate stones or gravel are frequent in period 2 and occasionally in period 1. Gout should be suspected with renal colic or nephritis.

Gout is still with us. Its rightful incidence is from 5 to 8 per cent of cases in an arthritic clinic.

DISCUSSION

DR. L. MAXWELL LOCKIE, Buffalo It seems that gout is more common in certain localities of the United States than in others. Around Buffalo and western New York State a fairly high percentage of gouty patients are seen in the average run of arthritic patients. In the greatest number the diagnosis can be strongly suspected because they present a typical history pattern. This is apparent after a few minutes' conversation. The blood uric acid is above the normal range in the big majority. It is well for one to be suspicious of gout in all male patients who have arthritis in whom there is some evidence of kidney insufficiency. Concerning therapeutic tests, no drug is so specific as colchicine, which acts so well to abate an acute attack. It has been observed that patients with gout are likely to develop an exacerbation if a high fat diet is given. With a change to a high carbohydrate diet the symptoms subside in from twenty-four to forty-eight hours.

DR. EDWIN P. JORDAN, Chicago I should like to ask Dr. Hench two questions. First, Does he think gout may start in the second stage without an attack of acute arthritis? I have had patients who had exacerbations of arthritis which at the time answered all the other criteria of gout but which did not let up between attacks. Second, Does he think the few cases of gout in families are on a hereditary basis?

DR. M. HENRY DAWSON, New York Since the appearance of Dr. Hench's paper several years ago I have looked for cases of gout in the clinic but only rarely have they been encountered. One, of course, sees more cases in private practice. However, I have wondered whether there may not be a geographic factor which may account for the varying frequency of gout in different parts of this country. It is well known that the incidence of gout varies greatly in different parts of Germany and Austria.

DR. R. GARFIELD SNYDER, New York I agree with Dr. Dawson that, if a high uric acid is considered an indication of the presence of gout, typical gout is relatively rare in New York City. I have seen only four cases of true gout in the last five years and only one case of tophi in fifteen years. In these four cases of gout over a period of five years the uric acid figures varied between 3.5 and 6.6 mg. per hundred cubic centimeters of blood, but as a rule the uric acid remained between 3.5 and 5 mg. I have seen a large number of cases in which, from the history and appearance of the patient, one cannot help suspecting gout. These patients have usually been on self-imposed diets with rigid restriction of red meats before coming for examination, and for that reason their blood uric acid figures are often within the normal limits. These I classify as atypical gout. Is it not reasonable to assume that a blood uric acid of from 3.5 to 5 mg. in cases of this type is indicative of or presumptive evidence of the presence of gout? I should like to ask Dr. Hench what method he uses to determine the amount of uric acid and what in his opinion is the lowest figure at which a case could be classified as gout. I have seen a few cases in which an acute attack of gout has been induced by the consumption of an excessive amount of sweets. Had Dr. Hench had any similar experience?

DR. J. ALBERT KEY, St. Louis I should like to ask Dr. Hench whether because a man has recurrent attacks of pain in the feet one should consider it a case of gout, or does he have other evidence? Naturally, since gout is so rare in the East and in St. Louis and is seen so frequently in Rochester, I suspect that most of his cases are not gout at all but are merely patients with foot strain.

DR. RUSSELL L. HADRY, Cleveland In a small group of patients in our urologic service who came because of prostatic obstruction four were immediately relieved by relief of the back pressure on the kidneys. Uric acid should be considered whenever prostatic obstruction is present.

DR. PHILIP S. HENCH, Rochester, Minn. When a patient comes with a history of a number of attacks of acute arthritis with complete remission but who has reached the stage where the attacks last six or ten weeks and when after a few days of a regimen of value only in gout he is running around entirely free from pain regardless of the presence or absence

of tophi, what else can we call it but gout? We have had this experience repeatedly, often with cases of tophaceous gout, which I believe would be accepted as true gout even in New York or St. Louis. The factor of heredity in gout is probably important, but it is not of much help in diagnosing gout in our American patients, for it is rare to find one who knows of any gout in his family. Regarding age incidence, gout does occasionally appear in young adults and from Europe come reports of gout in male children, but, in the majority of our cases, acute gouty arthritis first appeared after the age of 30 or 40 years. I believe that the fewer cases of gout in women included in any one series, the more accurate the diagnoses of gout probably are, and if an investigator states that many more than 5 per cent of his patients with gout are females, his criteria of diagnosis are open to question. In one German series of about 300 cases, about 35 per cent of the patients were females. In several hundred cases of gout seen at the Mayo Clinic, only three patients with tophaceous gout and about fifteen with presumptive (pretophaceous) gout were women. In each case the history was the same as that for males: recurrent attacks with complete remissions. At the clinic a normal concentration of uric acid in the blood is considered to be less than 4 or 4.5 mg. per hundred cubic centimeters (Folin method, 1930). Many patients with early gout have a normal concentration of blood uric acid, and there are other causes for hyperuricemia than gout. Quick recently summarized them as follows: states in which ketosis arises, such as in fasting, in severe diabetes and on a high fat diet, states in which an excessive accumulation of lactic acid may arise, such as in eclampsia, chloroform poisoning, pneumonia, circulatory failure and various other conditions of anoxemia, or with lactic acid feeding, after ingestion of excessive amounts of sodium bicarbonate, in severe renal disease, and after administration of benzoic acid, phenylacetic acid and numerous other aromatic acids that decrease uric acid excretion. To this list should be added leukemia and polycythemia. In most series of carefully studied cases of gout, tophi have been found at any given time in only about 40 to 50 per cent. It is foolish, however, to wait on pathologic proof (tophi) for a diagnosis of gout. If one is content only with a pathologic diagnosis, that is almost analogous to waiting for a stroke before diagnosing arteriosclerosis, or for a uremic convulsion to make a diagnosis of nephritis. We have used the provocative (high fat low carbohydrate diet) test for gout proposed by Lockie and Hubbard. It is useful but not consistently positive. When definite provocation is obtained, unexplainable on other grounds, gout is present in all likelihood, since this test diet does not seem to aggravate cases of atrophic or hypertrophic arthritis. It should be settled whether it is necessary to obtain ketosis before the diet will provoke gout. I have seen several cases in which unmistakable acute gouty arthritis developed while patients were on a ketogenic diet for the treatment of urinary infection with colon bacilli. I cannot confirm Dr. Snyder's experience. I have not seen gout provoked by candy or other excess of carbohydrates. According to Lockie's experiments and the opinion of Quick, an excess of carbohydrates should benefit gouty patients and tend to prevent attacks. An exception might be a patient with a double metabolic fault—one with gout and diabetes. When a gouty patient consistently fails to respond to a regular gout regimen, adhered to faithfully, experience has led me to hunt for some other metabolic disturbance complicating the gout, such as latent or unsuspected but active diabetes or an abnormality in thyroid function. I have studied several patients with both diabetes and gout in the past two years.

Differential Diagnosis of Periarticular Fibrositis and Arthritis

DR. CHARLES H. SLOCUM, Rochester, Minn. Fibrositis is the commonest form of acute or chronic rheumatism. Statistics of the British Ministry of Health show that 60 per cent of 2,500 insured patients with rheumatic disease had fibrositis. It occurs in association with gonorrhea, gout, rheumatic fever and atrophic arthritis but its real cause is not known. It is believed to be due to some unidentified infection or toxin.

A tentative classification based on etiologic grounds might be 1 Primary fibrositis independent of any other disease due to infection or toxemia—nonspecific fibrositis 2 Secondary (fibrositis) to some known cause, as trauma, gonorrhea, rheumatic fever, gout or influenza The clinical and pathologic features are still incomplete

Primary fibrositis is anatomically classified thus 1 Intramuscular fibrositis, or "muscular rheumatism" 2 Periarticular (capsular) fibrositis 3 Bursal fibrositis, "bursitis" 4 Tendinous fibrositis, "tenosynovitis" 5 Perineural fibrositis, "sciatika" These may have a common pathologic basis

The first stage is truly inflammatory The second is indurative with subcutaneous nodules and local thickenings of fibrous tissue. In the third stage the induration goes or remains as painless nodules with contractures Intramuscular and periarticular fibrositis are common types Slocumb finds that a fourth of his primary cases are intramuscular and a fourth periarticular Lumbago, torticollis, pleurodynia are examples Periarticular (capsular) fibrositis is mistaken for atrophic arthritis because it is indefinitely associated with use of the capsule or pressure on it and thickening occurs without x-ray evidence. The chief symptoms are stiffness on rising and in damp weather, and fatigue without any essential abnormality Nodules may appear over the elbows, the knuckles, and sacro-iliac or occipital regions Vagrancy of symptoms is characteristic of fibrositis and it may leave no deformity as compared with arthritis Fibrositis does not attack the joint cavity but it often occurs with infectious arthritis, synovitis, chondritis and osteitis The clinical incidence of fibrositis and atrophic arthritis are similar in age, onset, sex, bodily types affected and prodromal symptoms

Atrophic arthritis is, however, polyarticular There is articular tenderness, the stiffness is objective as well as subjective, muscular atrophy is common and swelling is present with fluid in the joint cavity Not one of these is characteristic of fibrositis Arthritis has few complete intermissions Exercise makes it worse, its symptoms are constant, more fixed and chronic There are more systemic manifestations, as fever, tachycardia, lowered blood pressure and loss of weight in atrophic arthritis than in fibrositis Fatigue and nervous exhaustion because of continued activity are marked in proportion to the objective evidence of disease in fibrositis Sixty-two per cent of Slocumb's patients with arthritis lost weight, 47 per cent lost more than 10 pounds (4.5 Kg), only 7 per cent of those with fibrositis lost more than 10 pounds Of the 100 patients who had fibrositis, seventy-eight who had suffered a total of 284 years of their disease presented no intra articular roentgenographic alterations, although thirty-seven patients were 45 years of age or older Hypertrophic arthritis was coincident in 22 per cent of the cases Even after twenty-five years of periarticular fibrositis, the roentgenograms were negative. In contrast, in 84 per cent of cases with atrophic arthritis there were definite roentgenographic alterations Although half of the 100 patients had had their disease less than a year, only 14 per cent of the entire group gave negative roentgenograms The greatest laboratory differences were observed in the sedimentation rate In fibrositis it was normal in 73 per cent, slightly altered (from 16 to 25 mm) in 16 per cent, significantly altered (from 25 to 32.5 mm) in only 11 per cent It was never more than 32.5 mm.

In atrophic arthritis the average rate was 71.5 mm Although 25 per cent of the arthritic patients had had their disease less than six months, only 3 per cent had normal rates Only 6 per cent had rates between 16 and 25 mm 91 per cent had rates more than 25 mm In 67 per cent the rate was more than 50 mm and in 23 per cent it was between 100 and 150 mm High rates were noted early in atrophic arthritis Blood counts were of differential value only in the concentration of hemoglobin in fibrositis Five per cent were less than 13 Gm in atrophic arthritis Forty-two per cent were less and 19 per cent less than 12 Gm

The differential diagnosis between fibrositis and atrophic arthritis depends then on finding synovial hydrops and roentgenographic changes with inflammation in the joint in arthritis

Fibrositis is extra-articular, characterized by arthralgia, stiffness and periarticular thickening Indirect evidence is afforded by the sedimentation rates of erythrocytes, and the estimation of hemoglobin and the weight curve is significant The differential diagnosis in favor of periarticular fibrositis is made on the persistence with which evidence of intra-articular disease remains absent

DISCUSSION

DR PHILIP S HENCH, Rochester, Minn. If gout in America is a forgotten disease, fibrositis is an unknown disease, at least it is not known by that name The disease is widespread in England and America, but little is written about it in this country and the term "fibrositis" is practically unrecognized here. In the three F volumes of the Surgeon General's *Index Catalogue*, fibrositis is unlisted as such in two of them, in the other volume (volume 5, third series) there are only fourteen articles on the subject Appearing between 1912 and 1922, all but two of these reports came from England What, then, is "fibrositis"—a new disease or a new name for an old disease? The term was introduced in 1904 by Gowers and by Stockman to indicate an inflammatory hyperplasia of white fibrous tissue anywhere in the body The several anatomic forms of this disease have been wandering around, separate and unclaimed, hunting for their common parent Some of these anatomic forms have long been called by Osler and others "indurative headaches," "cephalalgia," "capsular rheumatism" or "pleurodynia" A newer term is Albee's "myofascitis," which condition so commonly affects the lumbar and lumbosacral areas The intramuscular form is the layman's "muscular rheumatism," the general practitioners "myositis" But these are poor terms and less accurate than "fibrositis" because the disease does not primarily affect muscle cells themselves but is an interstitial, not a parenchymatous, disease of muscles The obvious outward evidence of this is the lack of significant muscle atrophy in primary fibrositis At first the clinical features of periarticular fibrositis (the jelling phenomenon, pain in stretching the capsule, the seasonable and weather effects, the vagrancy and variability in the pain, and other features) may seem vague and indefinite, but careful attention to the oft repeated story will show the features to be consistent and sufficiently distinctive so that the disease can be differentiated from "arthritis" which the uninitiated call it, and from "nervous exhaustion," which the unsympathetic are apt to call it Varying degrees of chronic nervous exhaustion and fatigue are practically always present, but the exhaustion is part of the disease—a symptom of fibrositis, just as another type of chronic nervous exhaustion is a symptom of hyperthyroidism The patient with periarticular fibrositis at first usually gets little sympathy He may complain bitterly but he looks well, his physical examination, laboratory tests and roentgenograms are generally quite normal, and his joints are undeformed and freely movable. It is then that his condition is apt to be called just *neuromuscular pain* or *psychalgia* These anxious, unhappy patients continue on their aching but undeformed way, almost more annoyed than pleased that the 'deforming arthritis' which they so fully anticipate forever seems to be postponed If the expected deformities would only appear, if they could "only get it over with," they would be almost more satisfied than to have this 'sword of Damocles' forever hanging over their heads But it is this persistent negativity of their examination that should convince one that arthritis cannot be present This negativity is relative however, for there may be some periarticular thickening, and in about 50 per cent of the cases definite subcutaneous nodules are palpable, most commonly in the region of the sacro-iliac or iliac crest When nodules are absent, some believe the diffuse muscular pains to be a neuralgia or sensory nerves of muscles Thus, the weakness of my presentation and that of others is the meager data available on the pathology of the disease as it affects muscles, but particularly joints Our studies on pathology to date seem to give histologic evidence that a true arthritis is not present in periarticular fibrositis and that the integrity of interarticular tissues is indeed maintained

DR JAMES R TILLOSON, Lima, Ohio What relation has occupation to this condition?

DR. WILLIAM J. KERR, San Francisco In the hospital is a man, aged 32, who for ten years has had some rigidity of the spine and in recent weeks some involvement of the muscles of the face, arms, thighs and calves. When one examines the lower extremities in the region of the gastrocnemius muscle, he may find rather elongated areas that are somewhat firm. The patient can find them more rapidly than the physician at first. In one instance the firm area was about 4 inches in length and one-half inch in thickness. In attempting to secure a biopsy of this nodule in the gastrocnemius muscle I had a great deal of difficulty. I thought it was just beneath the external surface of the muscle but had to go very deeply to get any tissue that seemed to be abnormal in appearance. This tissue showed the same characteristics as have been mentioned here. I believe five or six nodules were found. In Great Britain it seems to be the practice among some physicians to break up these nodules forcibly.

DR. M. HENRY DAWSON, New York The nodules in fibrositis are painful, while the nodules in rheumatoid arthritis are rarely if ever painful. I am of the opinion that the histologic structure of the rheumatoid nodules is quite distinctive.

DR. RUSSELL L. CECIL, New York The disease spoken of as fibrositis is much in need of a more substantial pathologic background. Take the condition commonly known as acute lumbago, which often follows a strain or some unusual movement, some of these attacks are caused by wrenching a joint that is already affected by arthritic changes, as shown in the roentgenogram. There are other instances in which congenital anomalies of the spine produce the same sort of attacks. Then there is a condition often spoken of as myositis or fibrositis in which the x-rays failed to reveal any change in the back except some defect in posture. A great many of these posture cases are quickly cured and relieved of future attacks by improvement of the posture. All orthopedic men are familiar with this type of case. I wonder how many of these cases should be spoken of as "fibrositis." I wonder whether most cases of myositis or fibrositis of the lumbar region cannot be classified as mechanical maladjustments of weak backs due to the posture of the patient.

DR. CHARLES H. SLOCUMB, Rochester, Minn. Regarding occupation, in England, as will be seen in the chart reproduced from Buxton, 55 per cent had fibrositis. The people that came to Buxton were miners and workers in factories, where they got cold and damp. I believe from those figures that patients with fibrositis are definitely made worse in cold, damp places. The reference to the breaking up of the nodules is a good one. Stockman and others use a firmer massage for patients with fibrositis than for patients with arthritis. Dr. Dawson commented about the nodules. The nodules in infectious arthritis and fibrositis are practically the same. Many of the nodules in fibrositis are not tender. In connection with Dr. Cecil's question regarding whether or not attacks of lumbago and muscle soreness are actually myositis or fibrositis, I cannot answer. There is a need for considerably more pathologic work in some of these cases. However, there is a large group that clinically and pathologically are fibrositis rather than myositis or arthritis. As far as the effect of the endocrines is concerned I cannot link definitely any endocrine deficiency with primary fibrositis.

Differential Diagnostic Points of Conditions Mistaken for Arthritis

DR. WILLIAM J. KERR, San Francisco Because the terms rheumatism and neuritis are loosely used many less common conditions in medicine must be discussed.

Syphilis Arthritis occurs early and late and even in congenital syphilis. The lesions are bilateral, not painful and of long duration. In congenital syphilis dactylitis of the fingers rarely of the toes is common. Chronic bursitis and myositis of the calf and sternomastoid muscles are observed. Periostitis, meningeal generalized aches and pain occur. Later the central nervous system and sensory roots cause peripheral pain. Charcot joints are present. Spondylitis is common with radicular symptoms. The history, other lesions, serologic tests and the x-ray examination establish the diagnosis.

Hemophilia Bleeding from the synovial membrane is common and arthritis and deformity occur, especially in the elbow and knees. It occurs in the male before puberty with the history of a "bleeder." The clotting time is prolonged greatly and the platelets are normal in number. The bleeding is normal and the clot retracts normally.

Scurvy Joint bleeding occurs in the general tendency to bleed. The periosteum near the joint may be elevated in the roentgenogram. Hemorrhages are general. The gums are spongy. There is a tendency to purpura. The remarkable effects following the use of vitamin C will support the diagnosis of scurvy.

Beriberi The dry or polyneuritic form due to the deficiency of the antineuritic vitamin may confuse with its pain and weakness of the extremities. Paresthesias, impaired sensations, weakness and tenderness of the muscles occur. Suspected deficiency and response to treatment help in the diagnosis. The cardiac complications may be striking.

Rickets Wasting of muscles, pallor and swollen epiphyseal line with the costochondral nodes (rosary) are diagnostic in children. The calcium loss is general.

Raynaud's Syndrome, Scleroderma and Arthritis These are frequently associated, probably through poor circulation. Scleroderma of the fingers impedes circulation progressively. Raynaud's always causes thickened skin and swollen, flexed joints of the fingers. Roentgenograms generally show demineralization of the bones and acral destruction as in leprosy.

Leprosy Paresthesias and loss of tissue in the digits occur late, but early the mixed nerve symptoms resemble Raynaud's syndrome and scleroderma. Enlargements and biopsy are diagnostic.

Cervical Rib and the Scalenus Anticus Syndrome This causes circulatory disturbances and radicular symptoms. Changes in color, swelling of the joints and necrosis of the digits may be striking. The shape of the thorax and neck is suggestive. The onset in middle life with increasing weight, stooping and pulmonary emphysema contributes to the symptoms. Arthritis or scoliosis in the lower cervical spine causes changes in the hands through the nerve roots.

Erythralgia Formerly erythromelalgia, erythralgia is pain and burning, discolorations and swelling with the feeling of warmth in the extremities. The arteries pulsate. Stasis causes the burning. The joints are secondary with fixation from disuse and contractures following.

Peripheral Neuritis This condition from alcoholism or toxic conditions is common. Arsenic poisoning, primary anemia and diabetes cause sensory or motor symptoms. Trichinosis and dermatomyositis are mistaken for arthritis at times. Intermittent claudication, fallen arches and Paget's disease are confused also. Periarteritis nodosa may resemble the activities of rheumatic fever. The history and complete examination usually give the diagnosis.

DISCUSSION

DR. JOHN H. MUSSEY, New Orleans There are several conditions which are frequently associated with pains in the joints. The first of these is anemia. The pains may be due not to the deficiency in vitamin diet to which Dr. Kerr referred but to the anemia. The pain in the joints is common without any roentgenologic evidence of arthritis. Stiff and painful shoulder, for which there were some sixteen causes is a condition in which it is hard to make an etiologic diagnosis. In a child who develops arthritis following an injection of serum in the first twenty-four hours it becomes quite a problem to determine whether that pain is the result of the injection of serum some seven to ten days previously or whether it is part of the complications of say the associated meningitis. I have noted quite a few people with angina whose referred pain confined itself to the elbow. I was particularly fortunate some time ago in having a man who complained of pain in his left elbow after he had taken exercise. An electrocardiogram was made and the curve was that associated with coronary disease. On treatment of the coronary disease the pain in the elbow disappeared. I think that the important lesson Dr. Kerr points out is that one must not be satisfied to diagnose arthritis without a thorough survey of the patient.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Electrosurgical Obliteration of Gallbladder Without Drainage—Experimental studies for a number of years have convinced Thorek that, if one could substitute a dry, nonleaking surface for the discharging cavity as the gallbladder bed represents following cholecystectomy, it would be a great step in the right direction. This thought has been brought to fruition by electrocoagulation. If a flat electrode of bipolar current is firmly applied to a tissue surface and a current of proper voltage and sufficient amperage is permitted to pass through it, dehydration and coagulation of the tissue proteins results in a few seconds. On the other hand, if the same electrode is not applied firmly or, if used as a unipolar or even bipolar instrument a small air space (dielectric) intervenes between the electrode and the tissue, sparking fulguration and carbonization with black discoloration of the tissues result. A reapplication of the electrode to such fulgurated or carbonized surface will stop further current penetration and prevent coagulation from taking place. The author evolved his method of cholecystelectrocoagulation on the basis of his experimental researches and clinical studies, the underlying principles of which consist of (1) biterminal electrosurgical obliteration of the posterior wall and bed of the gallbladder by electrocoagulation, (2) because of the great tendency of electrocoagulated surfaces to become agglutinated with serous surfaces, muzzling of the falciform ligament into service by completely detaching it from the anterior abdominal wall and (3) strict avoidance of drainage. Up to April 1936 he has performed this operation

in 181 consecutive, unselected cases of gallbladder disease including gangrenous, empyematous, sclerosed and other forms of pathologic disorders of the gallbladder. There was one death. Postmortem examination showed that the patient died from causes unrelated to the operation. Kellogg used the method in sixteen cases without a death, while Finlayson operated on four patients with good results. This brings the total number of operations performed to 201 cases.

Glove Flap Method of Dorsal Hand Repair—Following a burn from gasoline, O'Connor used a glove flap replacement on a hand of which the dorsum and fingers as far as the distal phalangeal joints were covered with a thick, heavy, red, painful, nonelastic keloid scar that prevented finger, thumb and wrist flexion. The entire scar on the dorsum of the hand and fingers was excised. A surgical glove was placed on the hand and sutured along the denuded edges. The portion of the glove covering the defect was cut out, a pattern of the hand defect was made on the right side of the abdomen and the donor flap and seven pedicles, one for each finger and one for the ulnar and the radial side were elevated by sharp dissection. The center flap and pedicle were made as thin as possible. The abdominal bed was skin grafted and then the injured hand was placed in the abdominal pocket and the flap pattern sutured to the hand. The digital pedicles were amputated in seven days, the ulnar pedicle in five days more, and the radial pedicle in one week more. The flaps were cut off under local anesthesia and sutured into their respective places and at the time of freeing from the abdominal wall complete take of the abdominal skin grafts was observed. The entire dorsum of the hand and fingers was covered in nineteen days, with a hospital stay of twenty-two days. By using elastic traction seven days after the last operation, a complete range of active finger motion was quickly obtained. At the present writing sensory nerve return has taken place.

Effect of Cervicothoracic Sympathectomy on Headaches—Love and Adson reexamined patients on whom operations on the cervical and cervicothoracic portions of the sympathetic nervous system had been performed for conditions other than headache in order to determine the effects of such operations on patients who complained of headaches in addition to the primary disease. They found that 75 per cent of eighteen patients who complained secondarily of headache were either partially or completely relieved of the headaches when bilateral cervicothoracic sympathectomy (according to Adson's technic) was performed for some other condition. Sympathectomy was most effectual in relieving headache when it occurred in association with Raynaud's disease. The relief of headache coincident with relief of a known vasomotor disturbance (Raynaud's disease) lends support to the view that severe headache occasionally, and migraine frequently, is the expression of a vascular

crisis related in some way to a disturbance of the sympathetic nervous system. It is apparent as a result of this study that cervicothoracic sympathectomy is effective in relieving a certain number of patients of periodic attacks of migraine. When a patient with migraine presents other symptoms indicating disturbance of the sympathetic nervous system, such as Raynaud's disease, cervicothoracic sympathectomy gives relief in about 75 per cent of cases. Cervicothoracic sympathectomy is justified in carefully selected cases of severe migraine.

Studies of Somatic and Autonomic Nerves—Heinbecker and his associates found that the physiologic properties of human nerve fibers, of corresponding size and type, are practically identical with those of the ordinary laboratory animals, such as the monkey, cat, dog and rabbit. Certain differences exist between the various animals, including man, as to which type of fiber (for instance, the myelinated or the nonmyelinated post-ganglionic fibers in the cervical portion of the sympathetic trunk) is utilized to subserve a given function in the body. A certain degree of variation also exists in the distribution of fibers into the various branches of a nerve trunk innervating a given region. Owing to these complications and to the further possibility that the treatment of a nerve at operation without proper precautions is liable to affect its function on subsequent examination, the investigation of nerves as a means of diagnosis should include histologic, physiologic and functional studies, and the results should be interpreted in the light of the circumstances, pathologic and manipulatory, under which the material was obtained.

Electrical Hearing Aids for the Deaf—In investigating the differences of the various hearing aids Hartig and Newhart found that in the devices having as components a carbon microphone, a carbon amplifier and an ear fitting receiver there are important differences in the amount of amplification produced

and tremendous differences in the intelligibility ratings. The differences in performance do not depend measurably on the observed nonuniformity of response. Furnishing frequency response curves to the otologist with each hearing aid would be of no value. Of greater importance is a wide range of response, freedom from singular peaks of amplification and sufficient amplification. Of paramount importance is the actual aid that the user obtains in interpreting speech sounds and sentences correctly. Hearing aids having a low intelligibility rating were found to produce the greatest volume of noise by products (principal cause of the poor intelligibility), owing to nonlinear distortion. Portable hearing aids consisting only of a carbon microphone and receiver are largely ineffective because of insufficient amplification. The best means of determining the personal usefulness of a carbon microphone hearing aid of known merit for a given person is the discrete sentence intelligibility test. The authors employed the following method. An exponential horn with an opening of 22 inches (55.8 cm.) was provided at the throat with a tapered fitting so as to match the holes in the receivers of the hearing aids. The microphone of the hearing aid and a speaker were placed in one room, and a number of observers were placed in an adjoining room, with a door between, tests of sentence intelligibility and of syllable articulation were then performed. The method permits hearing aids of different performance characteristics to be differentiated.

Menstrual Hypoglycemia and Functional Dysmenorrhea—Tedstrom and Wilson discuss further the relationship of menstrual hypoglycemia and functional dysmenorrhea. They tabulate the results of their blood sugar studies during menstruation and the results of extra carbohydrate feeding in thirty-eight cases. In every case in which the fasting blood sugar was low, that is, below 80 mg per hundred cubic centimeters the individual had either menstrual pains of varying severity or complained of marked nervousness, irritability, weakness, extreme hunger or excessive desire for sweets two or three days preceding menstruation. The treatment of the patients with functional dysmenorrhea associated with a low fasting blood sugar or a low sugar curve during menstruation consisted of extra carbohydrate feedings beginning about three days before the onset of the menses and continuing through the first three days of the period. It was observed that better results were obtained if the extra feedings were taken at intervals of two or three hours during the day rather than larger amounts at longer intervals. Orange juice was the usual form of carbohydrate taken. Karo syrup, dextrose and cane sugar worked equally well. These extra carbohydrate feedings have relieved the premenstrual tension and the menstrual pain in about 80 per cent of the cases in which they have been tried. Eight patients have been given 25 cc. of a 50 per cent solution of dextrose intravenously with immediate relief of menstrual pain. If the pain returns it is usually slight and easily controlled by extra carbohydrate feedings. Since relief of the menstrual discomfort was also obtained by several patients with a normal blood sugar it seems wise to try this form of therapy in every case of functional dysmenorrhea.

Relation of Sinusitis to Arthritis—Littell believes that (1) sinusitis often serves as a most important and frequently unrecognized focus in the cause of rheumatoid arthritis, (2) the systemic disease may often be markedly alleviated or entirely arrested by its proper care and (3) the area involved in these cases is usually the ethmoid. Sinusitis of some degree is common in temperate climates. His chief interest in it as a source of systemic disease is less in the amount of sinusitis than it is in the degree of absorption. Since he has approached it in this way, he has had much less disappointment in the care of the condition. Absorption takes place largely from the ethmoid-sphenoid region. A few cases have shown systemic improvement following treatment of chronic maxillary sinusitis. The greatest benefits, however, have accrued from attention to the upper sinuses. Of the twenty cases of arthritis cared for in the last few years, the author has had only two serious disappointments. In one of these, antral hyperplasia alone was removed. The patient showed no improvement and progressed unfavorably. The second, a severe case with fever, has now cleared up, but only after a stormy three years in Arizona. Three have shown only slight improvement. The remainder have improved from approximately 75 to 100 per cent.

Subarachnoid Drainage for Influenzal Meningitis—Stribley reports a case of influenzal (Haemophilus influenzae) meningitis in which complete recovery was made during treatment with continuous subarachnoid drainage, by means of a ureteral catheter and intramuscular injections of an autogenous vaccine. Almost daily spinal punctures were being made until he read Love's report of continuous spinal drainage. The catheter was inserted on three different occasions. The first time it remained in place four days. In about two days it was reinserted and remained in place five days. After its third insertion it remained in place for thirteen days. The catheter drained directly into a bottle pinned to the side of the bed. The patient was cooperative and the tube did not have to be

cut off short. When the patient complained of too severe a headache, the end of the ureteral catheter was clamped off for a few hours with a small hemostat. The drainage of the spinal fluid always decreased in amount after the catheter had been in place forty-eight hours. Autogenous vaccine was administered intramuscularly on four occasions. 0.1 cc of a 400 million autogenous vaccine per cubic centimeter was given on the thirteenth day of drainage, 0.1 cc on the fifteenth, 0.15 cc on the seventeenth, 0.2 cc on the eighteenth and 0.25 cc on the nineteenth. Forced fluids and physiologic solution of sodium chloride, as well as dextrose, were administered on several occasions during drainage. Methenamine was given by mouth empirically. The organism was morphologically and culturally Haemophilus influenzae. The organism grew extensively on a blood agar medium but not on the ordinary mediums.

Contact Dermatitis Due to Goat Hair Report of Case. R L Kile St Louis—p 376

Studies in Contact Dermatitis—In principle, Grolnick's method for surface testing of patients who are sensitive to adhesive plaster consists in stamping out, by means of a glass tube, a ring of some liquid adhesive or fixing agent around the test substance and sealing this over by a disk membrane cut from some impermeable or nearly impermeable material. The materials suggested are plain cellophane and collodion (experimental), scrim cellophane and collodion (experimental), tracing paper and collodion (experimental), white single-faced rubberized cloth and duo liquid adhesive, rubber tissue and frisket type rubber cement. There exists a distinct need for a number of such substitute techniques for patch testing, as a combination suitable in one subject may be unsuitable in another. The author has obtained the best results with rubberized cloth and duo adhesive and suggests this as a starting point when the problem of adhesive irritation arises. In fact, he has found it entirely satisfactory to use this procedure in a routine way in testing for contact dermatitis. Cellophane, which is used extensively in the patch test as a constituent part of it, may be of the moisture-proof kind the surface coating of which contains a natural resin. This variety of cellophane may thus produce misleading positive reactions in selected instances.

The Mechanism of Migraine—For the last five years, Goltman has had a young woman under his care who has suffered with typical migrainous attacks for as long as she can remember. Her case is singular in that she has had her brain explored through a burr opening over the left frontal region. The observations made suggest the following points for consideration. 1 There is at first a vasomotor spasm, as evidenced by blanching of the face and persistence of the depression in her skull. Other features of the aura observed by others such as numbness and tingling, and eye symptoms, may be due to vascular spasm with subsequent temporary ischemia of the brain or parts of the brain. 2 There was secondary vascular dilatation with resulting edema of the brain, the severity and extent of which depend on the degree and duration of vasomotor stimulation. This swelling of the brain probably produces a temporary disproportion between the size of the cranial cavity and its contents, a condition in accordance with Auerbach's theory. Vascular dilatation and a wet brain were found on exploration. This evidences itself postoperatively by a bulging

in the left frontal region during a migrainous attack in the case reported. There is a temporary hypersecretion of cerebrospinal fluid, and hyperabsorption of cerebrospinal fluid occurs simultaneously with or immediately following hypersecretion. The cerebrospinal fluid is rapidly produced and is absorbed just as rapidly. According to Weed the passage of the cerebrospinal fluid into the large venous sinuses of the brain through the arachnoidal villi is purely a matter of filtration from a point of higher pressure to one of lower pressure. If this is so, with increased pressure within the subarachnoid space there must be a more rapid absorption of fluid. This hyperabsorption tends to equalize the pressure within the subarachnoid space.

Leukopenic Index in Allergic Diseases—Rinkel performed 537 leukopenic index tests in fifty-six different patients whose symptoms included hay fever, perennial vasomotor rhinitis, asthma, eczema, urticaria and migraine. He found that a postmeal leukocytosis was usually associated with foods not producing allergy, whereas leukopenia or an indeterminate count was associated with those producing symptoms. The accuracy of a single forty-minute count is about 80 per cent that of the three postmeal counts. Several cases of intractable asthma were cleared up promptly when the leukopenic index was used as an adjunct to other tests. The count was of especial value in these cases because clinical observations were misleading. In one case only two foods agreed according to the leukopenic indexes, and this was corroborated by having the patient live on these foods for two weeks and remain absolutely free from symptoms during this time. In one case of extreme asthma it was found possible to relieve cough and wheezing commonly thought to be due to emphysema. Asthmatic patients whose symptoms could not be controlled either showed a positive leukopenic index to all foods or were unable to maintain a negative leukopenic index to a food regularly used in the diet.

Remissions in Progressive Muscular Dystrophy—Conwell points out that in 1930, after four months of viosterol therapy for rickets a coexisting far advanced, progressive muscular dystrophy showed unexpected improvement. A search of the literature failed to reveal viosterol as a treatment for muscular dystrophy but considering his past failures with the disease he mentioned the incident to subsequent muscular dystrophy patients. Five or six patients elected to follow this regimen and in this group remissions have occurred. A history of a hereditary factor was unobtainable. The four children had been on faulty diets of their own selection. One adult had followed a low protein diet for a year and the other adult employed a well balanced diet but had been exposed to the sun very little for thirteen years. There was no uniformity in the dietary faults. Three months of treatment (from 6 to 30 minims [0.4 to 2 cc.] of viosterol daily) was usually necessary before improvement could be observed. No untoward reactions were noted. The return of motor power was incom-

plete in three and complete in three patients. Of the former one has relapsed, one is still disabled and one carries on about normal activity. The latter three patients have returned to normal activity and two have discontinued treatment, one for about two and one for four years, without signs of relapse.

Menorrhagia Occurring at Onset of Catamenia in Patient with Thrombopenic Purpura. Report of Case. A. Stern. Worcester, Mass.—p. 1147.

The Hypophysis and Resistance to Infections and Tumors—Houssay points out that the existence of a direct antitoxic or anti-infectious action of the pituitary gland or its secretions has not been proved but that the gland can modify the resistance of the animal by its metabolic action, its regulating action on the thyroid or adrenal and on the vascular or nervous system. It has been thought that the increased growth in typhoid convalescents or sexual retardation and amenorrhea in adolescent tuberculous patients may be due to functional changes in the gland, but as yet there is no proof of this. Anesthetics and hypnotics are not tolerated well by hypophysectomized animals, and after operation some species are more susceptible to infections, poisons of the nervous system (cobra venom, morphine, chloralose), blood pressure and blood sugar lowering agents (insulin, phlorhizin). Hypophysectomy, because it produces hypothyroidism, provokes a decrease in phagocytosis and accelerated formation of antitoxins (in dogs), the agglutinin production not being changed. The thyrotrophic hormone of the anterior pituitary by stimulating thyroid activity causes hypersensitiveness to anoxemia in rodents in the mouse an increased resistance to acetonitrile and in the dog a slightly increased resistance to chloralose occur. The pituitary can be the site of benign or malignant new growths also of metastases. The structure of the pituitary is modified in patients suffering from cancer. Hypophysectomy retards but does not prevent the growth of tumors and diminishes the number of implantations which take probably this is due to a metabolic action which should be studied. The urine of cancerous patients has a powerful gonadotropic activity. Pituitary extracts can accelerate the growth of certain tumors. In some cases the follicle stimulating factor has an inhibitory action but its specificity and its practical importance are doubtful.

*Rheumatic Heart Disease in Children H A Ruprecht Tulsa—p 207

Rheumatic Heart Disease in Children—Ruprecht points out that when the pediatrician thinks of heart disease he thinks first and foremost of rheumatism, which contributes from 80 to 90 per cent of all the organic heart ailments of childhood. It must be thought of as a generalized systemic infection, chronic in nature, characterized by periods of quiescence and exacerbations but exerting its most serious and ravaging effects on the heart. The initial infection of the rheumatic state occurs principally in childhood. About 0.5 per cent of the school population are affected by it. Of this number 64 per cent develop heart disease. The average age at which the primary rheumatic infection was acquired is 7 years. According to Stroud, at the end of ten years 40 per cent are either dead or totally disabled. Kaiser, however, found that only 8.2 per cent were dead at the age of 10 years. Davis and Weiss state that 5 per cent of all deaths due to rheumatic heart disease occur in the age period between 0 and 9 years, and 20 per cent between 10 and 19 years of age. Morse, in a follow-up study of 100 children seen during their first attack of "endocarditis" from ten to thirty years previously, found that thirty-six were dead, three were cardiac invalids and sixty-one were normal, alive and well. Of the sixty-one, thirty-seven had apparently normal hearts. He stated that death occurred early in a large proportion of the fatal cases. Rheumatic fever occurs most frequently among the lower economic class. The relationship between rheumatic fever and the streptococci is highly suggestive but still unproved. Prophylactic measures are limited to general hygienic measures, change of climate and possibly tonsillectomy, if done prior to the onset of the disease. Actual treatment still remains largely symptomatic and rest is the most important factor of all. Fever therapy is a promising addition to the older methods of treatment.

Skeletal Changes in Disturbances of Parathyroids—Hodges sketches briefly the phases of parathyroid function and dysfunction by discussing the state of calcium in the blood, normal parathyroid control of calcium, calcium regulation in hyperparathyroidism, calcium regulation in hypoparathyroidism, roentgen diagnosis of skeletal lesions in hyperparathyroidism and differential diagnosis. From clinical and laboratory studies on material of this sort, it is now generally believed that hyperparathyroidism, either spontaneous or induced, causes an

excessive amount of calcium and phosphate to pass from the bones into the blood, resulting eventually in the generalized skeletal condition known as osteitis fibrosa cystica or von Recklinghausen's disease. The removal of an abnormal gland or the cessation of extract injection slows up the outward calcium and phosphate tide, following which normal processes, only dimly understood, slowly return calcium phosphate to the bones until calcium ion concentration in the plasma falls to normal levels.

Lung Abscess Treated by Artificial Pneumothorax—Harrell adds seven cases of abscess of the lung to the sixteen that he reported four years ago as treated by artificial pneumothorax. Nine of the group were cured by this method alone, one patient died, while three came to operation, two of whom got well. In producing pneumothorax for a tuberculous lung, an endeavor is made to collapse the lung completely and hold it at rest until it heals. In acute abscess or suppurative conditions of the lung the objective is to promote and facilitate drainage, as it is through the process of drainage that pyogenic infections are thrown off and healing takes place. As soon as a diagnosis of lung abscess is made, small quantities of air should be injected in the pleural cavity to act as a buffer and prevent the lung from sticking. The wavelike motion through inspiration and expiration will continue and the lung will be in a better position to empty itself, and a larger percentage will recover in a shorter time. In his first series of sixteen cases, the shortest period under treatment was one month, the longest six months. In the second series of seven cases, one patient died of abscess of the brain, although from all appearances the lung was healing satisfactorily. Two died while under treatment, one from pulmonary hemorrhage and the other from lack of cooperation. Both of these were chronic cases and were refused by the surgeon. One came to operation and went on to recovery, the remaining three patients recovered, with an average of three months under collapse therapy. Two of three patients developed abscess following tonsillectomy under general anesthesia, one following operation on the stomach, one following the extraction of an infected tooth and one following pneumonia. Another had a very marked case of oral sepsis while the cause of the last was undetermined. In conclusion, complete recovery occurred in twelve cases, or 52.1 per cent under collapse therapy combined with rest, the highest percentage of recoveries given under any other form of treatment. The author claims that collapse therapy is the easiest, quickest and safest form of treatment that can be used in acute lung abscess.

*Polymyositis with Eosinophilia. Case. D. McAlpine—p. 238

Polymyositis with Eosinophilia—McAlpine cites a case of polymyositis that resembles dermatomyositis. The case is remarkable because of the high grade eosinophilia. A man aged 36, after malaise had pains in the lower limbs, followed later by swelling and hardening of the muscles. Weeks later the upper limbs were similarly affected with impaired movements of the fingers and wrists. The veins of the upper and lower limbs became prominent and pulsation developed in the cephalic veins. Six months after the onset the disease was still active, as was shown by pains in the trunk muscles usually associated with gastro-intestinal symptoms. Movements of the fingers and wrists were much restricted and the muscles, especially of the forearms, felt abnormally hard. No lesion of the skin was apparent except a diffuse brownish pigmentation over the forearms and legs. A leukocytosis and high grade eosinophilia (eosinophils 37 per cent) were present six months from the onset, these gradually became less marked as clinical improvement took place. Repeated examination of the feces failed to show a helminthiasis. Apart from an excess of streptococci in the feces no toxic focus was found. A small piece of muscle removed from the forearm showed mild inflammatory changes. Subsequently considerable improvement took place, so that the patient was able to return to work a year after the onset. A point of significance in considering the association between myositis and eosinophilia is the gradual diminution in the number of eosinophils corresponding with the clinical improvement; this suggests that the eosinophilia did not exist prior to his illness and therefore it can have been caused only by the infective agent or by some product of the myositis. It is suggested that the subcutaneous tissues and muscles became hypersensitive to some infective agent; it is possible that the infective agent was a streptococcus. This case may serve the purpose of drawing attention to the occasional association of myositis and eosinophilia in the absence of helminthiasis.

*Don't Treatment of Pernicious Anemia. Note. R. M. Murray Lyon—p. 329

Acid Ammonium Phosphate as Urinary Acidifier—Alstead states that acid sodium phosphate is of negligible value as an acidifier of the urine and that its use should be abandoned. Frequently it actually alkalinizes the urine and cannot be regarded as a suitable standard by which to assess the value of ammonium acid phosphate. Acid ammonium phosphate in doses of approximately 2 Gm. three times a day markedly diminishes the pH of the urine, and no further increase in the hydrogen ion concentration occurs with greater doses. Despite the administration of large doses of acid ammonium phosphate the pH of the urine never fell below 4.7 and the maximal acidity of the urine in the great majority of the patients was represented by a pH of about 5.5. Considerable elevation in pH was frequently seen, notably in three cases in which the ranges were pH 8.7 to

5.7, pH 8.5 to 5.8 and pH 7.8 to 5.2, respectively. In these cases the urine was already alkaline when the administration of ammonium acid phosphate was begun. In patients whose urine was previously fairly acid (about pH 6) the use of the ammonium salt produced comparatively little change in the hydrogen ion concentration. The saline cathartic action of acid ammonium phosphate appeared when the daily dose amounted to 17 Gm., i.e., about three times the effective dose for acidifying the urine.

Leuko-Erythroblastosis—McMichael and McNee discuss three patients, presenting themselves as examples of "splenomegaly of unknown origin" under the term "leuko-erythroblastosis." The blood picture in each showed the constant presence in the circulating blood of numerous immature red and white cells. The term seems more accurate than leuko-erythroblastemia (Vaughan 1934), since anemia may be absent and even polycythemia exist at a stage when the diagnosis may still be made. All three patients were women. All are dead, but a postmortem examination could be carried out only in one instance, in which death followed splenectomy. In the other two patients the disease ran its natural course and in both terminated with features of a hemorrhagic diathesis. These three cases have a common pathologic basis in the presence of myeloid metaplasia as the predominating feature of the microscopic appearance of the spleen. Associated with this extramedullary hematopoiesis is the occurrence of erythroblasts and myelocytes in the circulating blood. The disease appears to be uniformly fatal and its course is relatively uninfluenced by roentgen treatment, liver therapy and splenectomy. In the postmortem examination one striking feature was the apparent absence of much active marrow in the long bones. This disappearance of marrow tissue was not due to any serious sclerosis or fibrosis in the marrow cavity, for there was ample room among the fat spaces of the marrow for local increase of hematopoietic tissue. Why such extensive extramedullary hematopoiesis should be found in the presence of a bone marrow which in places was almost aplastic it is impossible to say. In the clinical diagnosis of a leuko-erythroblastosis, leukemia is the most difficult condition to exclude. Chronic myelogenous leukemia nearly always shows some degree of erythroblastosis as a hematologic feature, but it is found that the number of erythroblasts seldom reaches 5 per cent of the number of myelocytes and is usually much less. In leuko-erythroblastosis the proportion of nucleated red cells is usually much higher than this and may range from 5 per cent of the myelocyte figure to a number far exceeding the myelocytes. The leukocyte count does not reach the high figures so common in myelogenous leukemia, 58,000 being the highest encountered and figures exceeding 40,000 being unusual. In early cases the differential diagnosis may be extremely difficult. Failure of the spleen to diminish appreciably in size to roentgen treatment is a helpful diagnostic point. When a tentative diagnosis has been made it is then time to search for a cause, especially in the bones and bone marrow. Failing that, no etiologic factor is known.

Vitamin B₁ in Treatment of Polyneuritis—Russell has treated cases of chronic progressive polyneuritis, alcoholic neuritis, subacute combined degeneration of the spinal cord and patients suffering from anorexia with parenteral injections of vitamin B₁ with good results. In cases showing peripheral nerve degeneration the shorter nerves, to the proximal parts or the extremities, are least severely damaged and show rapid recovery following the administration of the vitamin. Parenteral administration of the vitamin is of advantage as thereby any risk of destruction of the vitamin in the alimentary canal is obviated. It is of advantage also for purposes of diagnosis as the response when deficiency is present is strikingly rapid.

Hypertension Produced with Benzedrine—Peoples and Guttman wished to find what mental changes will take place in normal or mentally abnormal persons when their blood pressure is altered artificially. They made experiments with benzedrine on twenty-five persons. The drug was given orally in doses between 10 and 80 mg. In each subject the normal daily fluctuation of blood pressure was recorded and the mental state was carefully considered. There were only two persons who did not show any reaction to the doses used. The lowest dose to which any one reacted appreciably was 20 mg., twenty-two patients reacted to 30 mg. There was no blushing or pallor and no alteration of the size of the pupil, gastro-intestinal motility, perspiration or genito-urinary function. In the seven cases in which blood sugar readings were made during the experiment there was no fluctuation beyond the normal limits. Respiration was unaffected. In some cases the appetite was less during the action of the drug, and about one fourth of the subjects reported dryness of the mouth. The latent period after the administration of the drug generally lay between forty-five minutes and two hours. Once the action on the blood pressure had become apparent, the maximal point was reached in about an hour. The decrease was gradual, the normal pressure was reached between two and five hours after the peak, according to the dose given. The blood pressure always became normal within twenty-four hours after the administration of the drug. The intensity of the reaction apparently depends on several factors, the most important of which was the amount of the drug administered. Persons with low and labile pressure reached more than those with higher and more stable pressures. The pressure changes were chiefly systolic, the diastolic showing little or no increase, so that there was an increase of the pulse pressure. The acceleration of the pulse usually lasted longer than the increase of the blood pressure. The majority of the subjects found difficulty in going to sleep and woke much earlier than usual. The first psychic symptom after the administration of the drug was talkativeness especially in depressive patients, they overcame their retardation, and several of them talked spontaneously to other people for the first time since their admission. Improvement was also visible in the patients' movements. Some of the normal subjects showed a motor restlessness. The most interesting feature was a change of mood, experienced in nearly every case. In no instance was anxiety produced or a depression deepened. The change was generally in the direction of euphoria. To demonstrate some features of the complex mental changes, sixteen patients were given the Kraepelin continuous addition test before and during the intoxication, and in some cases control experiments were made at various times. Nine showed an increase in the number of additions far beyond the probable error and the normal increase by practice, and the rest had only slight increases or none. This drug is promising, but it cannot be used until it is known whether permanent administration produces anything like adaptation habituation or addiction.

Puerperal Surgical Scarlet Fever—Burton and Weir report three cases of puerperal scarlet fever none of which showed hemolytic streptococci in the throat, but all harbored them in the cervix. The organisms were all inagglutinable with the ordinary scarlet fever type scrums. The nose and throat of the doctor concerned and of those in attendance who were different in each case, were negative for hemolytic streptococci indicating that the disease was not a droplet infection. Puerperal fever without a rash when due to a hemolytic streptococcus, does not differ from puerperal surgical scarlet fever, except in the type of organisms in some cases and in the susceptibility of the patient in others. Definite benefit accrued

in each case from the administration of scarlet fever antitoxin. Although they do not admit of definite proof, the authors believe that the results would not have been so favorable had the cases been treated by any means other than with serum. Despite recently adduced evidence to the contrary, they are of the opinion that all such cases—and many others of puerperal sepsis, even when no scarlatinal rash is manifested—would be benefited by the early administration of an adequate amount of scarlet fever antitoxin.

Influence of Cod Liver Oil on Infected Wounds—Hayashi believes that the accelerated healing power of cod liver oil when applied to infected wounds is mainly due to the effect of vitamins A and D and the lipid contained in the oil. The effect should be attributed chiefly to the action of the lipid. The effect of vitamins, which has heretofore been regarded as the chief efficacious property, is not really as remarkable as that of lipid. The continuous application of cod liver oil for clinical treatment of wounds and bruises does not seem to cause any reactions.

Serum Reaction in Diagnosis of Leishmaniasis—Giraud and his co-workers carried out investigations on iron peptonate as a reactive for serum. The action of solutions of these substances on normal serums and serums from leishmaniasis patients furnished serologic reactions already known in kala-azar, but with increased intensity. The authors noted especially the specificity, constancy and sensitivity of the reactions obtained by various solutions. Two reactives were found superior to others. These were the iron peptonate powder of Merck and the iron peptonate solution of Robin. The preferable dilutions of these substances were respectively 1/600 and 1/320. They concluded that the reaction was definitely valuable in the diagnosis of leishmaniasis. Its consistency was remarkable and it was quite sensitive. When compared with other reactions that have been employed in the diagnosis of kala-azar, they believe that this method is superior.

Staphylococcus Toxoid—Debre and his collaborators discuss the use of anatoxin (toxoid) in staphylococic infections. The toxoid, like the staphylococic toxin flocculates in the presence of antistaphylococcus serum. This enables the accurate titration of various toxoids. The toxin injected in progressive doses into a horse produces in the serum of that animal a specific antitoxin from which an antistaphylococcus serum can be prepared. It is this serum which placed with the toxin, neutralizes its triple hemolytic, escharotic and lethal properties. They have by this means been able to produce a serum reaching a titer of 250 international antitoxin units per cubic centimeter. This serum when used in various staphylococic infections, was in many instances quite successful. They conclude that therapeutics with toxoid should be tried in the presence of any serious infection due to the staphylococcus. General reactions characterized by fever and profound malaise do sometimes occur but in their experience have never taken alarming proportions. Local reactions are almost the rule but in only a few instances are severe enough to indicate cessation of treatment. Focal reactions are impressive and can sometimes be noted by the patient. In view of these occasionally disturbing possibilities they believe it a good rule to give a preliminary intradermal injection of 0.1 cc. in most staphylococic infections. The results are good but are at present uncertain in severe infections and pyonephrosis and are unfavorable in osteomyelitis. The interpretation of the results remains difficult especially in view of the fact that many spontaneous recoveries occur.

Detection of Yellow Fever by Examination of Liver—It has been recognized for some time that histologic examination of the liver might reveal the evidence of latent yellow fever. Thus Hoffmann has insisted since 1928 that the degenerative lesions of the liver are an extraordinary and so specific that they allow a positive and certain diagnosis. Babelt believes that the histologic examination of a fragment of liver fixed in 15 per cent maldehyde and stained will give an entirely characteristic picture. The characteristic degeneration and the necrosis

are especially characteristic. Practically, the elective distribution of the cellular degenerative lesions in certain regions of the lobule carries a positive diagnosis of toxic hepatitis due to yellow fever. In the absence of a serologic method allowing the positive diagnosis of yellow fever and the failure of experimental inoculations, postmortem viscerotomy and histologic examination of the liver must be considered the most effective measures of reaching a positive diagnosis.

Hemorrhage in Uvula—Schoenlank reports the history of a man, aged 49, who always had an attack of coughing in the morning (chronic pharyngitis). One morning he had an unpleasant foreign body sensation. The retching caused lancinating pains radiating backward and upward in the throat. The feeling of discomfort increased to severe dyspnea and the patient tasted blood on the tongue. When after about thirty minutes he came up for examination, the uvula showed a balloon-like enlargement, so that it touched the pharyngeal wall, left only a small opening between the tonsils and the palatine arches and rested on the tongue. The uvula was violet-blue-red. In the upper third, on the left side, it had two small tears and there were lighter spots from which blood had escaped. The portion of the uvula resting on the tongue was edematous. The enlargement of the uvula was caused by a hematoma, which was punctured and suctioned off. In order to decrease the edema, 10 cc. of a 20 per cent solution of calcium gluconate was injected and ice packs were prescribed. These measures counteracted the dyspnea and gradually also the difficulties in swallowing. This type of disorder was first described in 1853. It has been mistakenly referred to as Rosvies's disease, for when that author described a case in 1911 he believed his report to be the first.

Osteochondritis Dissecans of Elbow—Pezcoller reports a case of osteochondritis dissecans of the elbow in which the osteochondritic fragment removed was formed by two parts which were slightly united. The portion which was separated from the epiphysis was necrotic and that which was united to the epiphysis retained vitality and vascularization. Connective and fibrocartilaginous cells were newly formed near the epiphysis and a process of regeneration of the necrotic spongy substance of the fragment which was united to the epiphysis was evident. It is obvious that the detached portion of the fragment passed through the same process of attempted regeneration before its separation from the living parts of the epiphysis had taken place. In connection with his case the author discusses the several pathogenic theories of osteochondritis dissecans which he believes originates in necrosis of the epiphysis that first involves the spongy substance of the joint then the bone marrow and lastly the articular cartilage. The formation of new cells may result in regeneration of the spongy substance early during evolution of the disease but connection of the surrounding structures acting as local trauma produces first a fracture with partial detachment of the involved part from the epiphysis and then as the pathologic process evolves complete detachment of the fragment which turns into an intra-articular body. Prognosis of osteochondritis dissecans in regard to functional and anatomic recovery is

the involved joint, is good provided operation is performed early and before complete detachment of the fragment takes place. Once the latter is formed, arthritis deformans is the next complication. It is advisable not to scrape the joint during the operation, because this may cause local alterations, which may result in development of articular malformations. The route of approach for performing the operation is selected according to the seat of the osteochondritis focus.

Tubercle Bacilli After Nephrectomy in Renal Tuberculosis—Ravasini investigated the presence of tubercle bacilli in the urine of fifty-six persons who had undergone nephrectomy for unilateral renal tuberculosis. No tubercle bacilli were found in the urine of the twenty-two patients in whom nephrectomy had been performed more than four years previously. Tubercle bacilli were found in the urine of sixteen (47 per cent of the cases) of the group of thirty-four patients who had had nephrectomy performed less than four years previously, and in 66 per cent of the cases in the group of patients who had had nephrectomy performed less than one year and a half previously. The presence of tubercle bacilli in the urine after nephrectomy is more frequent in men than in women in a proportion of twenty to one.

III Effects of Carbon Suspensions Injected Intravenously—For a few years, satisfactory results have been reported by some writers from the use of intravenous injections of animal carbon suspensions in the treatment of various infections. Martella made experiments on dogs to verify the changes produced by the animal carbon. The doses used were proportional to those used in the treatment of human subjects. The results of microscopic study showed that carbon particles

accumulate in the lung, liver, brain and, in smaller quantity, in the spleen and in the kidney. The largest quantity of carbon accumulates in the lung, causing occlusion of capillaries, precapillaries and small blood and lymph vessels, carbon is also found in a free state in the pulmonary cells and the lumen of the alveoli. It accumulates in Kupffer's cells and in the leptomeningeal capillaries and small blood vessels of the choroidal plexus in smaller amount than in the lung. Vascular lesions and inflammatory processes, hemorrhages, neoformation and degeneration of tissues are the most frequent alterations produced, especially in the lung and the brain. The author considers the treatment harmful.

Congenital Deformities of Limbs. F Garcia Dñinx.—p 439

Diagnosis of Ascites and Ovarian Cyst—Sancho Castellano says that in some cases metrosalpingography gives sufficient data to establish a differential diagnosis between ascites and ovarian cyst. By mechanical action ovarian cysts, the uterus and sometimes the fallopian tube of the side on which the cyst is located caused dilatation of the efferent urinary organs, displacement of the ureter and of the uterus and sometimes of the tube of the cystic side to the opposite side of the cyst. Ascites, regardless of its quantity and etiology does not exert any mechanical action on those structures. The author performs a functional test of the kidney by the parenteral injection of indigo carmine. Delay in the time of appearance of the stain in the urine points to probable obstruction of the urinary tract and to the immediate performance of metrosalpingography in which a quantity of from 7 to 12 cc. of 40 per cent iodized oil is used. The injection is made slowly and with the minimal pressure. Once the uterus is filled, the oil passes to the tubes. The typical metrosalpingographic picture of ovarian cyst shows displacement of the body of the uterus and sometimes of the tube of the involved side to the opposite side. The displacement of the uterus in malignant ovarian tumors associated with ascites is slight and there is an upward deflection of the tubes. Bilateralism of the uterus in tuberculosis of internal genital organs associated with ascites is a retraction to either side rather than a displacement, and the uterus is fixed. In these cases the tubes are obstructed by the inflammatory process. In cases of parovarian cyst the uterus is displaced to the opposite side of the cyst. The metrosalpingographic picture of parovarian cyst is identical with that of tuberculosis of the internal genitals. The differentiation of these two conditions is made by the immobility (retraction) of the uterus in tuberculosis and propulsion of the cyst in the lateral culdesac in cases of cysts. The diagnosis made in the author's cases was verified by operation.

- *Calcium Therapy and Calcium Prophylaxis in Lead Poisoning. A. Schretzenmayr and G. Bauer.—p. 479

Vitamin C and Gastro-Enteritis—Einhauser points out that vitamin C is stored in the wall of the small intestine, in the liver, in the adrenals and in the anterior lobe of the hypophysis. In the wall of the small intestine it seems not merely to be a question of storage, but it is probable that vitamin C has a particular function to perform. The author cites observations which indicate that vitamin C fulfils a detoxicating and a protecting function in the gastro-intestinal tract. The author studied the vitamin C metabolism in persons with gastro-intestinal disturbances. He made tolerance tests with cevitic acid. To patients with gastro-intestinal catarrh who received a diet with constant vitamin content he gave daily 30 mg. of pure vitamin C either in the form of tablets by mouth or by intravenous injection. In nearly all patients this tolerance test revealed deviations from the behavior that is observed in normal persons. Moreover, there were differences in the vitamin C elimination according to whether the vitamin C was administered enterally or parenterally and whether the patient had an anacid or a hyperacid form of gastric disturbance. The utilization of vitamin C was most noticeably disturbed in patients with anacidity. The cause for this is to be found in the more rapid oxidative decomposition of vitamin C in the more alkaline intestine of the patients with anacidity and in the capacity of their pathologic intestinal flora to destroy vitamin C. The vitamin C requirements of the organism are, as a rule, inadequately supplied in patients with gastro-intestinal catarrh. It is possible to counteract this deficiency in from one to two weeks by administering cevitic acid in the usual therapeutic doses (300 mg. daily).

Calcium Therapy in Lead Poisoning—Schretzenmayr and Bauer observed in animals with lead intoxication with the characteristic symptoms of severe anemia and loss of weight that the intravenous administration of large doses of calcium improves or cures the otherwise fatal disorder. They observed that the symptoms of lead poisoning are suppressed and the animals are practically protected against lead poisoning if simultaneously with the dose of lead they are given large doses of calcium. On the basis of these experiments the authors discuss the possibility of the therapeutic and prophylactic use of calcium in human lead poisoning.

Micromethod for Weltmann's Reactions—Havas shows that the customary technic of Weltmann's coagulation reaction requires comparatively large quantities of blood which have to be obtained by venesection. The author has devised a micromethod which works with one tenth of the quantities. From 11 to 12 drops of blood that is approximately 0.5 cc. is withdrawn from the tip of the finger and following coagulation is centrifugated. Then 0.15 cc. of serum is carefully drawn off so that there is no admixture of erythrocytes. The serum is put in a small test tube and 1.35 cc. of distilled water is added.

After serum and water have been thoroughly mixed, they are distributed into twelve test tubes (0.1 cc. each). Then 0.4 cc. of the electrolyte solution is added to each tube, beginning with the twelfth and going up to the first. After shaking the tubes are placed into the boiling water bath and fifteen minutes later are withdrawn again. The reading is taken either at once or, at the latest, after one hour and the coagulation band is recorded. It is advisable to make five or ten tests simultaneously, for this greatly simplifies matters. The author points out that, because tuberculous patients usually do not show extreme variation, the method can be further simplified by setting up a series of only nine test tubes instead of the usual twelve, omitting numbers 1, 2 and 12. However, if complications are suspected (pneumonia, new, exudative pleurisy, peritonitis and so on), the full series of twelve should be set up. The author thinks that in other disorders the series may likewise be shortened. He says that the test was made on approximately 500 patients with tuberculosis and that the coagulation band proved a helpful aid in the clinical evaluation of these cases. He admits, however, that the reaction is of value only in connection with other clinical methods and after several repetitions.

- Postappendicitic Peritonitis Complicated by Intestinal Obstruction with Recovery After Jejunocolostomy and Cecostomy. K. Haugseth.—p. 624

Hemorrhages in Brain in Wood Alcohol Poisoning—Berner says that in the five fatal cases of intoxication from wood alcohol here reported and one earlier case he established hemorrhages at the base of the fourth ventricle, in one case macroscopically visible. The arteries in this localization thus seem especially sensitive to the irritation produced by wood alcohol. Hemorrhages at the base of the fourth ventricle in a case of intoxication from illuminating gas are also described. Attention is called to the characteristic extent of these hemorrhages, before the acoustic striae and close to the medial sulcus analogous to traumatic hemorrhages, and to the fact that his examinations of the brain fixed in solution of formaldehyde afford favorable conditions for close observation. The observations are seen to agree with the clinical picture in intoxications in which respiratory paralysis usually occurs directly after blindness. In a case of poliomyelitis, hemorrhages similar to those in traumas and intoxications were found.

Stricture of Splenic Vein—Rø describes the case of a girl suffering from violent periodic vomiting of blood usually with out warning, following trauma of the epigastrium at the age of 10. In the course of six years, marked secondary anemia appeared, improvement resulted from iron medication but blood transfusions seemed to have an unfavorable or only temporarily favorable effect. There was a varying enlargement of the spleen more marked during the quiet intervals. Roentgen examination showed probable varices in stomach and esophagus. Splenectomy was advised but refused. Death occurred from hemorrhage. This instance gives a characteristic picture of splenic pylephlebotomy, the designation used by Wallgren for all obstacles in the portal system expressed by enlargement of the spleen, periodic hematemeses and anemia. The disease occurs mainly in children. The stenosis occurs as the result of obstacles of different anatomopathologic kind and with varying localization in the portal system and is classified as intrahepatic, truncular or radicular as in the case discussed. Common to all is a secondary formation of thrombi which aggravates the unfortunate circulatory condition. The importance of trauma as an etiologic factor is emphasized. Treatment is either medicinal or operative. The results of treatment are best in children. Prognosis is grave without an operation. The patient may live upward of ten years.

RECENT ADVANCES IN GASTRO- ENTEROLOGY

CHAIRMAN'S ADDRESS

ERNEST H. GAITHER, M.D.
BALTIMORE

A wide diversity of opinion exists among the members of the American Medical Association as to what disease or group of diseases may constitute a specialty, this nonagreement is particularly marked in the case of diseases of the abdominal organs.

In any field it is essential that there should be a number of men thoroughly trained in every detail and keen not only to keep abreast of all advances in research but also to make original contributions in clinical and laboratory studies. A body of such specialists whose advice is available to practitioners lacking opportunity for comprehensive study in that line of work is not only invaluable but indispensable.

It is my intention to set forth in this paper my own considered opinion as to what gastro-enterology as a distinct specialty involves, together with my ideals as to preparation for the handling of this branch of our profession, and progress during the past decade. In the future as in the past, I shall actively oppose narrow specialism in any branch of medicine, there can be no doubt that such an unfortunate state has arisen and continues to exist, to the inevitable detriment not only of specialism but also of medicine as a whole.

The term "stomach specialist" is of course anathema, I myself dislike "gastro-enterologist" as well, it is at once too narrow and too vague. I prefer to be considered a properly trained internist who is devoting himself especially to diseases of the abdomen having both direct and indirect relationship with the digestive organs. By what properly descriptive term this specialty shall be called is as yet a moot point.

There are manifested in various parts of the abdomen, on many occasions, troublesome symptoms that are not caused by intra-abdominal disease but by extrinsic lesions in tissues, a single organ or a group of organs, in such cases a man untrained in the special study necessary to a diagnostician of diseases of the digestive tract and the abdomen as a whole will find himself woefully inadequate, and an improper diagnosis may easily result in dire consequences to the unfortunate patient.

I feel very strongly in regard to this, considering it essential that a man be required to give proof of adequate and comprehensive training in internal medicine, and of thorough study in the domain of abdominal disease before he may declare himself a specialist in this

vital subject, he should by all means be submitted to tests by those best fitted to pass on his qualifications before he dare assume a title so hardly earned and so highly esteemed by men who have devoted themselves to research in this field.

RECENT WORK

One of the most stimulating recent publications is the monograph by Faber, in which he clearly sets forth his own views and those of other eminent authorities as to proofs of the presence and frequency of both acute and chronic gastritis. His report on the method of preparing the tissues in order to prevent postmortem changes, his statements as to the effect of acute infectious diseases on the gastric membranes, the relation of acute and chronic gastritis to superficial and deep erosions (the latter finally leading to chronic ulcer), the relation of acute gastritis to hyperacidity, the chronic stage to anacidity and later pernicious anemia, the fact that chronic gastritis may and often does precede ulcer and carcinoma—all his points are most interesting and worthy of consideration, no matter what our opinions may be with regard to these vital problems.

He makes the arresting statement that in his researches he found a large percentage of anacidity among the relatives of patients suffering with pernicious anemia. He believes that one always finds very pronounced signs of chronic inflammation in patients with chronic anacidity, also that in pernicious anemia there is an advanced gastritis with or without severe atrophy of the mucous membrane, further, that pernicious anemia can exist without anacidity, finally, that it is possible to see acid secretion start again in certain cases under treatment. He quotes Hurst as stating that in no less than four cases he has seen the acid secretion come back in pernicious anemia while the stomach was under lavage treatment, and the anemia thereafter disappeared. He develops many other interesting theories on this subject.

It now seems opportune to call attention to the studies of Bloomfield and Pollard on the secretory function of the stomach, these studies are convincingly presented in the monograph "Gastric Anacidity." These authors have made innumerable researches, and I feel it important to quote the summary of Bloomfield's study on clinical aspects of gastric secretion.

Because of the wide variations in gastric secretion which are found in healthy people, it is difficult to draw conclusions of diagnostic value in patients. In practice, measurement of gastric secretion is helpful in the diagnosis of pernicious anemia and perhaps certain types of hypochromic anemia—of gastric and duodenal ulcer, and of cancer of the stomach. The routine employment of test meals even in the case of patients with indigestion, is useless, whereas an occasional well conducted measurement of gastric secretion performed to aid in solving a special diagnostic perplexity is sometimes of the greatest value.

Undoubtedly one of the most brilliant contributions of recent years is Castle's demonstration that pernicious anemia is usually due to the absence of an essential gastric secretory substance commonly associated with achlorhydria.

Hollander has lately conducted a splendid piece of research regarding the composition of pure gastric juice, in this connection should be mentioned the thorough and excellent studies by Martin, Granturco, Quigley, Lehrman and Nelson have also made outstanding additions to the literature on the physiology of digestion.

Greengard, Maison and Ivy have isolated a substance from the intestinal mucosa which is free from objectively detectable toxic factors, it inhibits gastric secretion and motility in the dog and is known as enterogastrone. The authors state that it may prove to be of practical value because it possesses the gastric inhibitory attributes of atropine without its undesirable secondary effects and may thus be advantageous in certain cases of peptic ulcer.

Dragstedt and his associates have contributed a valuable article, "The Pathogenesis of Acute Dilatation of the Stomach", this should appeal both to internist and to surgeon.

Rehfuß has done notable work in popularizing and simplifying the fractional study of gastric secretion, he has carried on many other studies, which culminated in the recent publication of his textbook, entitled "Medical Treatment of Gall Bladder Disease". I must emphasize in this connection the work of Lyon on gall-bladder drainage, it is based on the work of Meltzer, an eminent leader in physiology of the digestive tract, and Lyon has lately incorporated his own researches in a monumental treatise, "Atlas on Biliary Drainage Microscopy".

The development of the flexible gastroscope accounts for much progress and is destined to play an increasingly important rôle in diagnosis of diseases of the stomach, Schindler has been a leader in this field and is now making further exhaustive studies. Many investigators are following in his footsteps, and it is to be predicted that within the next few years our knowledge of gastric pathology will be vastly expanded.

As to syphilis of the stomach, the original works of Clasen and of Eusterman, published not long ago, present the subject in the ablest possible manner and are to be heartily recommended, as are also the excellent papers by O'Leary, Moore and Aurelius, Biscoe issued last year a thorough study of this lesion of the stomach, and Pusch gave an interesting review of thirty-five selected cases. While the contributions to the literature in this field have not been extensive, they are too numerous to be included in full in this limited paper.

Pain is an old, old subject yet ever new, and while much of real value has been written, I may refer especially to Christensen's fine monograph 'Pathophysiology of Hunger Pains' and to the recent publications of Boyden, Rigler and Rivers dealing with localization, genesis and probable pathways of pain, certain it is that much remains to be learned concerning the details of pain mechanism in visceral disease.

The relation of allergy to gastro-intestinal changes and symptoms continues to make splendid progress under Rowe, Duke, Vaughan and other investigators and all this work promises to be most helpful in diagnosis and therapy.

The question of the etiology of peptic ulcer still baffles and intrigues us all. Nothing of a definite con-

clusive nature is as yet forthcoming, and no less eminent an investigator than Ivy has discontinued studies on the subject. In a late issue of the *American Journal of Digestive Diseases and Nutrition*, Smithies gives a comprehensive review of the various current theories concerning the etiology of peptic ulcer.

With regard to the treatment of peptic ulcer, the early work of Sippy and Smithies must be considered while their views and methods differed greatly, both were true pioneers, and on a basis of their efforts much useful knowledge has been gained. Smithies has been a prolific contributor to the advancement of gastroenterology in all its aspects, and his latest achievement has been the publication of the review to which I have referred.

The capacious cup of literature is brimming with productions having to do with the parenteral treatment of peptic ulcer. The various remedies proposed are legion, the most popular at this time are those containing histidine and nonspecific protein. Many workers are extremely enthusiastic over the results obtained, but I feel that we should postpone final evaluation until a far greater number of cases have been treated, over a longer period.

Sara Jordan and her associates have produced what seems to me incontrovertible evidence for the efficacy of conservative or orthodox therapy for the healing of a large majority of peptic ulcers, the contribution is a splendid piece of clinical research. However, a continuation of comparative studies by both methods should be encouraged.

The inaccessibility of the small intestine has greatly handicapped morphologic, secretory, chemical and bacteriologic study of this part of the digestive tract; hence comparatively little work has been available to students in this field, however, certain methods of investigation have recently been adopted, and these will undoubtedly lead to more rapid progress in research.

Certainly the excellent studies and methods being perfected by Grier Miller and his associates relative to the intubation of the small intestine will be of the greatest aid in the study of secretion, absorption, motility, bacteriology and chemistry of this portion of the digestive tract. Gray has lately presented the results of an elaborate research, "The Influence of Some Organic and Inorganic Acids on the Motility of the Small Intestine". A very fine study, "A Symposium Concerned with the Duodenal Factors in the Neutralization of Acid Chyme," has been made by Mann, Imes, Stevens, McRoberts and Hoerner, this forms an admirable addition to the data on physiology of the small intestine, and the relation of pancreatic secretion. A valuable clinical study by Barger and Guthrie is "The Effects of Drugs on the Motility of Isolated Segments of the Intestine of Man". In the category of works on the small intestine should be mentioned the article by Alvarez and Hosoi, "Conduction in Different Parts of the Small Intestine". Mackie and Pound, and Ravdin and his associates, must also be congratulated on their important studies in this subject.

Crohn presents a splendid piece of work, "Regional Ileitis," claiming the discovery of a new disease entity. As in all such cases, speculation is rife as to whether this is really a new disease or the ultimate outcome of a specific or nonspecific infection with changes of an ulcerative nature. Bockus has also written an exceptionally fine paper on this subject. An extended period of experimentation in a larger number of cases will be needed before a final decision can be reached.

Thoughtful consideration must be given to Felsen's assertion, based on exhaustive clinical research, that chronic idiopathic ulcerative colitis, and regional ileitis, represent the end result of bacillary dysentery.

Bargen has done a colossal piece of clinical and laboratory work on ulcerative colitis, he asserts that this disease is due to a specific organism and reports remarkable success following treatment by vaccines and serum, in conjunction with proper hygiene and diet, and a certain amount of drug therapy.

In direct opposition to the claims of Bargen are the views expressed in the equally excellent studies of Paulson, who believes that ulcerative colitis is not due to the specific organism described by Bargen but is caused by a variety of organisms, as well as other factors. Now appears Sullivan with a paper which merits consideration because it attacks a question which is in the minds of many at this time, namely, the effect of psychogenic factors in the production of somatic diseases, the title of this provocative work is "Psychogenic Factors in Ulcerative Colitis."

Hurst of London, an honorary member of the American Gastro-Enterological Association is a prolific contributor of extremely valuable work referable to the digestive tract, and his "Constipation and Allied Intestinal Diseases," written some years ago, remains an outstanding classic.

Study of the colon has been intensively followed, and so many have been the splendid publications that a complete list would require all my allotted space.

The various phases of liver activity continue to provide an alluring array of problems to the solution of which many eminent scholars are devoting time and study, the number of publications showing encouraging results is so great as to preclude specific mention. I must note, however, Ivy's achievement in isolating a new hormone, cholecystokinin which exhibits a specific action on the gallbladder, such a substance should offer great therapeutic possibilities and may ultimately prove helpful in diagnosis.

I shall touch briefly on the progress of liver function tests. On the liver devolves so wide a range of duties that as yet no single really dependable procedure, diagnostic of function as a whole, has been perfected. Yet, thanks to our indefatigable explorers, we have available methods which are useful under varying conditions and in certain diseases, and the application of two or more of these will in many instances furnish us with well grounded diagnostic information. The tests now in greatest favor are the van den Bergh coagulation time, sedimentation, galactose tolerance, brom-sulfalein, rose bengal and Takata-Ara.

Snell and Plunkett made a detailed clinical research in order to determine the diagnostic value of the hippuric acid test, they concluded that the rate of synthesis of hippuric acid is a reasonably accurate and satisfactory test for the determination of parenchymatous hepatic damage, particularly in the "surgical types" of jaundice. Excellent progress is being made in this domain and the caliber of the men exploring this subject is an assurance of ultimate success.

In regard to studies of the pancreas stimulating achievements can be reported. The names of Ivy, Mann McClure Gamble, McIver, McCaughan Martin, Silverman Liman, Le Sage, Dragstedt and Babbitt loom large as untiring investigators, that many other valuable workers must be omitted from the list is due to limited space, not to a lack of appreciation of their notable contributions.

Various accepted reliable methods of estimating enzymatic activity were comprehensively presented in the June 1934 issue of the *American Journal of Digestive Diseases and Nutrition* by the Enzyme Committee of the American Gastro-Enterological Association, this committee is of the opinion that further comparative studies of methods, especially for the determination of activity of the proteolytic enzymes, seem indicated, and the number of normal individuals tested should be increased until statistically accurate curves can be drawn.

Briefly, the committee concludes that enormous variations in enzymic activity occur normally, that the presence of amylase in duodenal juices does not prove its pancreatic origin, and that the activity of the specific enzyme should be recorded in percentage of substrate converted to simple building stones, namely, sugar, amino acids and fatty acids. In the case of amylase the question of substrate (soluble starch) is relatively simple, but for protease and lipase the question of substrate deserves some study, the measure of lipolytic activity of the duodenal juices constitutes the most satisfactory test for pancreatic enzyme so far available, no standardized methods exist even among the authorities in the field, and it is evident that under existing conditions comparative value cannot be obtained. Therefore, if standardization is to be accomplished, study must be undertaken with each enzyme in turn. At present, the only diagnostic significance of enzyme concentration in the duodenal contents is the persistent absence of enzyme indicating obstruction of the pancreatic ducts, such as a malignant growth in the head of the pancreas, this can be revealed by any of the tests, especially that for lipase.

They recommend that outstanding authorities, each with selected co-workers, be appointed to study and prepare simple and more accurate lipase and trypsin tests, these to receive comprehensive application by a large number of observers, in order that a reliable standardization may be achieved.

I should call attention to the work of T. R. Brown on the relationship of migraine to a diet rich in carbohydrate, and the brilliant result often observed when a diet with minimal amounts of starchy food is applied. There is also his excellent presentation of the intimate relationship of hepatobiliary disease to cardiac function and symptoms, showing that many patients had been diagnosed and treated as cardiac cripples and veritable invalids, though later on removal of an infected gallbladder restored cardiac function, eliminated symptoms, and enabled these former chronic sufferers to recover normal health.

Dr Madge T. Macklin presented in 1934 a timely essay relative to heredity in disease, she is of the opinion that a knowledge of inheritance in disease is of utmost importance to any practitioner of medicine or surgery and that to no group is it more essential than those who make a special study of gastro-enterology. This article is most illuminating, and its subject is worthy of continued study by our members. Hurst has definitely committed himself to the idea that the constitutional factor diathesis plays an important role in predisposing an individual to certain diseases of the digestive tract.

It would be a congenial task to dwell at length on the efforts being put forth on behalf of the problems of nutrition and metabolism, of endocrine dysfunction related to the digestive tract, and the splendid progress made along a wide front in the study of sprue and

parasitic disease, indeed, there is no phase of our subject that I would not enjoy traversing in detail, and nothing would gratify me more than a complete roster of our able clinical and laboratory researchers and writers. The fact that my references must cover many years in a few minutes limits not only this survey but my encomiums, and all will sympathize with me in this dilemma.

It is possible to refer only briefly to the achievements of the past few years in roentgenologic study of the abdomen, but I wish to pay tribute to those who have made such inspiring progress in x-ray study of the digestive organs. Among the signal accomplishments are Kantor's "Colon Studies," particularly those studies relating to anatomic abnormalities, they have greatly added to our knowledge of this portion of the tract.

Mucosal relief was first brought to the attention of roentgenologists by Forsell in 1913, but it was not until about a decade ago that technic for its study began to be developed, it was then that Berg started his valuable work on the stomach and duodenum, making use of the compression method. Since that time Albrecht, Chaoul and Schatzki have published excellent papers, Schatzki, working at the Massachusetts General Hospital, has developed an equipment which is of great advantage in the diagnosis of early and small ulcerative lesions as well as the gastritides.

Improvement in the technic of introduction of a combination of barium sulfate and air has been particularly advantageous in studies of the colon and in the diagnosis of polypi.

"Polysography" is a method whereby triple exposures of the stomach are made on the same film, it is thus shown that peristaltic movements are absent in areas of inflammation and neoplastic involvement, this should prove helpful in diagnosis.

Kymography, which has been useful in cardiovascular examinations, is now being applied to the study of gastro-intestinal peristalsis, where it should be equally advantageous. Kirklin's studies of idiopathic pyloric hypertrophy and duodenitis merit consideration and praise.

New thorium-containing colloidal compounds have been introduced, but it is doubtful whether they possess any particular advantage over barium sulfate as a contrast meal.

Cholecystography has been of inestimable worth, at present, oral application of the dye is in greatest favor. Stewart recently introduced a most efficient method of intensified administration of the dye which greatly facilitates the visualization of the gallbladder and is especially effective as regards the density of the shadow.

Roentgenologic contributions to the study of the small intestine have been few as compared with the offerings concerned with other portions of the digestive tract, however, the pioneer work of Walter Mills receives our unflinching homage. Of late, Cole, Mackie, Kantor, Soper and others have furnished us with progressive work of exceptional merit.

Roentgenologists have recently given much attention to anomalies of the esophagus with special reference to the congenital short esophagus, splendid work has been forthcoming from Findlay, Kelly, Clerf and Manges.

COMMENT

Incomplete as this presentation has necessarily been, it must have made clear that the men working in the domain of diseases of the digestive tract are not con-

fining their efforts to a restricted field but are continually reaching out to explore all the areas that may conceivably influence that realm. They are constantly evolving new and useful ideas as to etiology, pathology, symptomatology, diagnosis and therapy, in every ramification of the digestive system, every factor bearing on the digestive tract has been considered, every phase of its manifold functions has been studied, and this great volume of effort furnishes us with not only many stimulating problems but also with clues for their final solution. All signs, indeed, point to ever higher pinnacles of achievement.

The recent advances in gastro-enterology have been of such magnitude and distinction that they engender in us a just pride and renew our determination to press forward toward our goal of perfection.

The fellow human beings who place their health, and thus their lives, in our hands, have the right to expect from us all the security that our high standards can provide. These standards can be maintained only if men who wish to enter the field of abdominal diagnosis are first required to submit their capabilities and accomplishments to the unbiased judgment of a thoroughly competent group of workers in this field, zealous for the welfare of mankind and the ideals of their profession.

THE SIGNIFICANCE OF NEUTRALIZING SUBSTANCES IN RESISTANCE AND RECOVERY FROM POLIOMYELITIS

PAUL H. HARMON, PH.D., M.D.
AND
HENRY N. HARKINS, PH.D., M.D.
CHICAGO

During the year just past, the attention of both the lay and the medical public has been focused on field vaccination studies aiming to prevent infantile paralysis. Even though these applications followed specific laboratory trial of recognized immunologic procedure, they were forced to an abrupt halt by the suspicion that a few cases were causally connected with the immunizing procedure.¹ At present it is believed that as a result of these experiences, a safer method of prevention should be evolved for clinical trial. At this point it is apropos to review the fundamental tenets on which these trials were based. While there have been reports of successful vaccination against other virus diseases there have been disappointments in both application and interpretation of experiments in this field. For example, while no one denies the advisability of active immunization during the incubation period of rabies, recent experimental studies have denied that such procedures lead to immunity against an infectious dose placed directly in contact with nervous tissue. As will be shown later, a similar question is involved in the interpretation of immunity to poliomyelitis.

From the Division of Orthopaedic Surgery, Department of Surgery, The University of Chicago.
Supported by a grant from the President's Birthday Ball Fund for Infantile Paralysis Research.

Read before the Section on Pediatrics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

The question might be raised whether man always acquires an effective immunity against poliomyelitis. In the United States and Canada during the past twenty years, seventeen cases have been reported of a second attack occurring years after a first, including two cases that we have seen.³ This is an attack rate of 11 per hundred thousand calculated from the 150,000 reported cases.⁴ While these data are not statistically significant, this is many times the average rate for these years. The rarity of the disease during the first year of life and the low incidence among adults point to a relative immunity enjoyed by these groups. The fact that a large percentage of individual serums of these groups neutralize the virus of poliomyelitis is now well established and is the obvious explanation of these low attack rates. Are the neutralizing substances an accurate expression of immunity in this disease? Can resistance be present in their absence? Can the nervous system be invaded by the virus in the presence of neutralizing antibodies (humoral immunity)? Are there other factors of defense against the virus (mechanical factors and tissue immunity)? The replies to these and similar questions would furnish a complete answer to the moot point of the efficacy of vaccination as it has been practiced, were the entire data known. In the following discussion we shall attempt an answer in the light of recent experimentation.

PATHOGENESIS OF POLIOMYELITIS THE ORIGIN OF INFECTION

The contributions of Fairbrother and Hurst,⁵ Jungeblut and others⁶ have established beyond peradventure that the virus of infantile paralysis travels largely, if not exclusively, in the body by neural pathways (reviewed by Faber⁷). Interruption of a neuron parasitized by the virus, either peripherally or within the central nervous system, blocks passage to the cells of the spinal cord and intervertebral ganglions, the essential site of the disease. The striking resistance to intranasal infection after intracranial section of the olfactory tracts⁸ is a demonstration of this thesis. It is considered that the nasal and pharyngeal areas are the usual if not the only site of entry of the virus. Under the experimental state of increased intestinal pressure and of direct contact with the myenteric nerves infection may occur, but these are conditions that never obtain in natural infection (reviewed by Flexner⁹).

Indeed, it is probable that many persons harbor the virus in the nasopharynx, it being in a more or less stable equilibrium with the host.¹⁰ Such conditions

postulate that traumatic influences or lowered resistance may allow the virus to ascend into the central nervous system. Tonsillectomy¹¹ and extreme muscular exertion¹² have been reported as precipitating an attack of poliomyelitis with the characteristic incubation period. The puzzling epidemiologic fact observed many times a year in the seasonal endemic poliomyelitis of this country, of cases occurring in isolated areas where personal contact can be excluded except through healthy intermediaries, may be explained by parasitization of the nervous system by virus carried in equilibrium with the nasopharynx. This hypothesis has already been confirmed by the isolation of the virus from the nasopharynx¹³ with subsequent development of infection (reviewed by Paul, Trask and Webster¹⁴). Kramer¹⁵ has reported the isolation of the virus from pooled specimens removed by tonsillectomy in a general hospital. Ponderous technical difficulties do not allow the easy multiplication of such observations. The finding of large numbers of adults in the general population who carry neutralizing substances in their blood against the virus of poliomyelitis¹⁶ is indirect evidence of the widespread dissemination of the virus.

Washings of the nasopharyngeal area from certain persons contain virus inactivating property.¹⁷ Whether this is correlated with antiviral properties in the blood is not definitely known but is probable. From the practical point of view there promises to be a method available to increase the normal resistance of the nasopharynx in preventing passage of the virus over the first and thirteenth cranial nerves. Treatment of this area by alum, by tannic acid, by trinitrophenol and by mercurochrome has been signally effective in the hands

of three groups of investigators¹⁸ of the experimental disease. Application of these measures for prophylaxis in man awaits only the opportunity. While there are other physiologic factors of resistance to this disease (reviewed by Hudson, Lennette and Gordon¹⁹), there are no other practical measures as yet suggested that are likely to be of value in the disease of man except the application of specific therapy.

The question of whether the disease and the infectious agent are entirely confined to the nervous system is of importance in the development of specific immune bodies, the virus neutralizing substances. There is evidence that the virus is encountered in the blood or cerebrospinal fluid only irregularly²⁰. Thus, the barrier that exists between the blood vascular system and the nervous system keeps the virus in the latter area. Lennette and Hudson²¹ have shown that transportation of the virus into the susceptible nervous system can occur after intravenous injection only when the virus is excreted onto the nasopharyngeal mucosa or when a freshly severed nerve is available. That visceral spread of the virus does take place is seen in the finding of the virus in the perfused spleen during convalescence¹⁹. Previous failures²⁰ to detect the virus in extraneural locations are perhaps due to the presence of virus-neutralizing substances in the blood, a point brought out by Lennette and Hudson²¹. Irregular extraneural outflow of the virus during the acute disease accounts for the variable appearance of neutralizing antibodies in convalescence (as already shown), which remains one of the startling peculiarities of this disease.

THE ORIGIN AND SIGNIFICANCE OF THE VIRUS-NEUTRALIZING ANTIBODIES

The blood of a surprising percentage of human and monkey convalescents seems to be devoid of neutralizing substances, a fact that has been masked by the earlier workers, who have made only a few observations in the recovery state. Only recently has the blood of a large number of human convalescents been examined and the full force of this fact become evident. These observations are summarized in table 1. The percentage of convalescents without neutralizing substances in the blood varies from 12.1 to 64.1. The latter group was thought to be exceptional because they were treated in the acute stage with convalescent and antiviral animal serums. Of the total of 183 human convalescents, 39.8 per cent were without antibody. Jungeblut and Smith²² have advanced evidence to show that the ability to form antibody both after an attack of poliomyelitis and in those without history of exposure is linked with blood type, group A having this property in least degree while group B contains the greatest number of individuals with neutralizing properties.

On the other hand, a larger percentage of adults drawn at random from the populace and who have had no obvious exposure to the disease, carry neutralizing substances in the blood stream against the virus. The incidence of antibody in this group ascends with increasing age. This fact led Shaughnessy, Harmon and Gordon^{10a} and Aycock and Kramer^{10b} to draw analogy to diphtheria and to postulate repeated subclinical exposure to the virus. The presence of these neutralizing substances was interpreted by these authors and many others as signifying the immune state. This such a hypothesis will stand in the face of the newer ideas of tissue versus humoral immunity is questionable. As quantitative data accumulate, the analogy to diphtheria may be drawn even more closely, as it is well known that a certain percentage of Schick negative individuals are susceptible to clinical diphtheria. Table 2 gives the number of "normal" persons, by age groups, who have been found to contain virus-neutralizing antibodies in the blood. We have purposely

TABLE 1—Convalescence from Poliomyelitis (Man) Without Neutralizing Antibody in the Blood

| | Serums Tested | Per Cent Negative |
|---|--------------------|-------------------|
| Aycock and Kramer ^{10b} | 41 | 12.1 |
| Schultz and Gebhardt ^{10a} | 4 | 50.0 |
| Shaughnessy, Harmon and Gordon ^{10a} | 14 | 42.9 |

| 66a 1932 personal communication | 30 (serum treated) | 64.1* |
| Jungeblut and Smith ^{22a} | 20 | 42.5 |
| Stokes J. Jr, Wolman I. J. Carpenter H. O. and Margollis J. Am J Dis Child 50: 681 1935 | 7 | 23.5 |
| Harmon P. H. and Harkins H. H. Fahey J. J. and Washbotten P. M. Proc Soc Exper Biol & Med 34 68a 1936 | 11 | 72.7 |
| Total | 183 | 39.8 |
| Average | | 39.8 |

* This percentage is slightly greater than the figures given by Howitt by virtue of our including as negative serums those which prolonged the incubation period. Such a phenomenon has been interpreted as partial neutralization by certain authors. We do not favor such an interpretation.

† These data are not suitable for analysis by age group, as they are abnormally weighted with adults.

omitted reference to those who have examined only a few serums, as even the numbers quoted are not of far reaching statistical significance.

No difference has yet been elicited between the virus neutralizing antibodies of "normal" human blood and those of convalescence²³. Although identical, as far as we know, there is a division in opinion as to their origin. Most investigators believe them to be the result of specific contact with subinfective doses of virus, but another group holds that physiologic factors of growth, maturation and menstruation as induced by endocrine activity are responsible for the production of some of the neutralizing substances (reviewed by Jungeblut and Engle²⁴). Hudson, Lennette and King¹⁹ have failed, however, to verify the experimental data on which this

latter theory rests. In short, they have been unable to find neutralizing substances in mature male or female monkeys or in females rendered artificially mature by treatment with extracts of anterior pituitary. The known slight resistance of adult monkeys to cerebral infection,²⁴ like the resistance of the New World monkey²⁵ and lower species of mammalia,²⁷ remains unexplainable by humoral factors. Epidemiologic facts point to lessened chance for contact infection of adults in poliomyelitis as well as in other infectious diseases (measles and scarlet fever²⁸), since significant numbers of adults contract the disease only after the epidemic is under way.²⁹

That contact with virus is alone the stimulation for antibody production has been largely borrowed by analogy to the experimental disease. Kramer³⁰ and Fairbrother and Brown^{10c} have placed on record actual instances in man in which contact with the disease led to the production of immune substance, while Trask and Paul³¹ have made similar observations on the abortive types of the disease. Whether inflammatory involvement of the nervous system is present in the latter types is not known. If absent, as some believe, there is stimulation of antibody production by extraneural virus. The opposite view that the abortive and nonparalytic types of the disease are a result of an adequate amount of preinfection antibody (for the current attack) is postulated by observations made by Eagles³² on serum pools from these three types of the disease used for treatment in the 1934 epidemic in Denmark, and by our titrations of serum during and after an attack.

The strongest argument against the need of a specific stimulus for production of virus neutralizing antibodies is the finding by Jungeblut^{28b} of their presence in commercial serums of such variable origin as diphtheria antitoxin, antivenoms, antistreptococcus serums and the serums from pregnant mares. Confirmation and extension of these tests are urgently needed. The origin of the virus-neutralizing principle in human placental extracts³³ is not certain.

A peculiarity of the virus of poliomyelitis that requires some comment at this point is its weak antigenicity. While antibodies and solid immunity are readily produced by nasal spraying with other viruses (e.g., St. Louis encephalitis and louping ill³⁴), similar experiments with susceptible monkeys do not even lead to the development of virus-neutralizing substances in the blood.³⁵ Subinfective or modified virus given by

the subcutaneous route seldom leads to immunity against intracerebral or intranasal infective doses, although virus-neutralizing substances are produced, particularly if repeated doses of the immunizing preparation are given (reviewed by Olitsky and Cox³⁶ and Gordon³⁷). Even the vaccines, lately in use, have not yielded experimentally significant quantities of humoral antibody in the hands of all workers.³⁸ The underlying cause of this poor antibody response may be the lack of antigenic mass, it being well known that many viruses remain active in logarithmic dilutions (vaccinia, herpes, St. Louis encephalitis), while the poliomyelitis virus rapidly becomes subinfective on dilution.

TABLE 2—Normal Persons with Neutralizing Antibodies for Passage Strains or Poliomyelitis Virus

| | Age Groups | | | | | | | |

| Totals | 60 | | 103 | | | | 209 | |
| Average | | 37 | | | | 58 | | 73 |

* 0-4 year groups included twelve rural children none of which neutralized. Tests on twelve infants also reported by these authors (J. Exper. Med. 52:457, 1930) but not included in the above. Ten (83 per cent) neutralized.

† Including two infants both neutralized.

While other viruses develop complement fixing, precipitating and agglutinating antibodies (review by Rivers³⁹), it has now become well established by reports of exhaustive work from several laboratories⁴⁰ that the neutralizing substance is the only antibody associated with contact or infection with the poliomyelitis virus. Skin tests for susceptibility have likewise been negative in the hands of most workers in this field.⁴¹

NEUTRALIZING ANTIBODIES DURING THE ACUTE DISEASE AND DURING CONVALESCENCE

From the foregoing account it is clear that neutralizing substances are developed more or less regularly in response to the artificial introduction of virus either into or beneath the skin. Brodie⁴² has already reported that under such conditions the response exceeds that produced by an attack of the experimental disease. The full implication of such facts is not apparent,

TABLE 3—Neutralization of Virus by Serum Early in Poliomyelitis in Comparison to the Convalescent State

| Patient | Age | Blood Group | Clinical Data | Day of Paralysis on Which Blood Was Taken | Ten Paralyzing Doses of Virus Neutralized by Serum in Dilution of | | |
|--|-----|-------------|---|---|---|--------------|-------------|
| | | | | | Initial Sample | Later Sample | Time Months |
| Convalescent | | | | | Serum Given Prior to Taking Blood Sample | | |
| D N | 8 | AB | Initial leg weakness full recovery | 6th | 1 10 | * | |
| J H | 12 | AB | Extensive residual paralysis in both legs and hips | 5th | 1 2 | 1 5 | 5 |
| P J | 2 | A | Paralysis of both legs residual in one leg | 5th | 1 1 | 0† | 4 |
| L P | 8 | AB | Bulbar with palatal paralysis | 5th | 1 5 | * | |
| E S | 10 | O | Paralysis of one arm and both legs residual one hip and quadriceps | 7th | 1 1 | 1 2 | 3 |
| M H | 7 | O | Paralysis of both legs residual both calves | 5th | 1 2 | 1 2 | 3 |

* Second blood sample not obtained.
† 1:1 failed to neutralize 1:5 neutralized latter probably a false positive.

‡ Nonparalytic case; date on which serum was drawn was the number of days after the onset of temperature.

§ Blood obtained one day before the onset of paralysis.

because there has never been an adequate survey made of the behavior of the neutralizing substances after either the experimental disease or the acute disease of man. This author's experiments indicate that neutralizing substances are present in the blood stream ten days after a single injection into the skin but do not reach their height until ten days later. While Kolmer, Klugh and Rule⁴³ have been able to demonstrate neutralizing antibody as early as four days after their first immunizing injection their experience is exceptional in the general field of the viruses since as a rule neutralizing antibodies are not demonstrable until a week after the onset of the acute disease or from ten to fourteen days after experimental inoculation.

It was our opinion that observations should be made on the level of neutralizing antibody as early as possible in the acute disease in man, and again later in the same cases in order to determine the actual effect of an attack of the disease on the level of neutralizing substance. Antibody level should, if possible, be correlated with the outcome of the disease to see whether there is a level that will determine a nonparalytic or mildly paralytic form of the disease. Table 3 summarizes the results of in vitro neutralization tests on the serums of fourteen patients⁴³ during an acute attack of the disease. Only eleven serums were available for testing from three to five months later. One patient⁴⁴ an adult, was observed to have a greater than average amount of neutralizing substance even twenty-four hours before the onset of paralysis. This observation appears to be the first on record of evolution of paralysis in man in the presence of neutralizing antibody. Seven of these cases were purposely selected after convalescent serum had been administered to see what effect, if any, the administration of such low titer serums had on the antibody level during the acute stage. The effects of passive transfer were in unimpressive evidence in only one patient (D R), but he had received 80 cc of serum on two occasions only three days and one day before the first blood sample was drawn. From the fact that three months later he was entirely without neutralizing antibody suggests that none was present prior to the attack. The severity of the disease and the amount of recovery (inversely proportional to the degree of permanent motor nerve cell damage) have no correlation with the level of immune substance either during the attack or during convalescence. It is quite unlikely that the high level of immune substance in patients B W, D B and W R C was the result of the current attack. The series, as a whole, implies that the disease may evolve in the presence of neutralizing antibody. This is quite clear in the instance of W R C, from whom serum was taken a day prior to paralysis. That a disease may occur while circulating antibody is present in the blood stream is not a novel conception, as such observations have been made both within⁴⁵ and without⁴⁶ the virus field. On the other hand, patients P J R S and B R demonstrate very little or no antibody in the blood at any time, yet the severity of the disease and the amount of permanent motor damage is not greater than in other cases of the series.

That the amount of neutralizing substance found in the early samples is the direct effect of the current attack is minimized by the irregular appearance of immune substance following the experimental disease induced by intracerebral inoculation in monkeys. In similar in vitro neutralization tests on monkey serums made in parallel with the foregoing observations in

43 We are indebted to the Illinois State Department of Health (Dr. Frank J. Jirka, director) for early reporting of cases and aid in securing these blood specimens. human cases we found neutralizing antibody not to occur until the sixth to the fourteenth day after paralysis, and then irregularly. Even after neutralizing substances were once present in a given animal they were absent on a later date in four of six instances. No neutralizing substances were observed at any time during ten days after the onset of paralysis in three of seven animals. One animal acquired these substances between the third and the eighth week after paralysis. Such results were independent of the test dose of virus used (three and ten paralyzing doses). Essentially the same facts were recently reported by Jungeblut⁴⁷ with similar materials. In this investigator's hands, two of three animals had no neutralizing substance two weeks after paralysis, three of six had none after a month, and two of six had none after two months. In spite of the lack of humoral antibody, none were affected by intracerebral reinoculation with a heavy dose of virus (five of eleven having no antibody at the time of retest). It thus appears that resistance to intracerebral reinoculation, which is universal in convalescent monkeys, does not depend on humoral antibody. In this connection, the experiments of Paul and Trask,⁴⁸ who showed monkeys to be susceptible to cerebral reinoculation by a recently adapted human virus when convalescent from an attack conferred by a passage strain and the converse, should be recalled. Some degree of evanescent cross immunity was, however, observed by them.

SIGNIFICANCE OF NEUTRALIZING ANTIBODIES IN SERUM THERAPY

That convalescent or other serum modifies the natural course of human poliomyelitis has yet to be conclusively proved (reviewed by Harmon⁴⁹). Evaluation of the many observations in this field are fraught with difficulty, since the severity and types of the acute disease vary from epidemic to epidemic and even in the same epidemic. Statistical analysis of certain large epidemics has failed to elicit favor for convalescent human serum, except that the earlier the serum is used in the acute stage the less is the incidence of either acute or residual paralysis.⁵⁰ Clinical observations that have been made by almost every group that has applied convalescent human serum of a rapid response by a drop in temperature and improvement in symptoms cannot be disregarded. It is questionable whether treatment of one group of cases with serum, withholding it from others, has been justifiable from either the administrative or the scientific point of view.

Experimental monkeys cannot be used to evaluate a serum to be applied in the human disease, since for reasons as yet poorly understood the disease of these animals is fulminating. The endemic types of the human disease are especially unlike the experimental counterpart, the former having a smoldering and often nonparalytic course. We⁴⁹ have pointed out that from 70 to 80 per cent of cases reported in epidemics before 1933 have been nonparalytic types. In certain recent epidemics,⁵¹ less than 10 per cent of the patients have

been paralyzed at any time. It is entirely probable that the preparalytic cases are seen in this stage because they are mild cases. For example, the general mortality in the epidemic of 1931 in New York City⁵² was 12.2 per cent, while among the preparalytic cases in which no serum was given the mortality rate was only 0.9 per cent. Attempts at evaluation of the effect of convalescent serum in the established disease of monkeys either in the preparalytic stage or in the stage of manifest paralysis have uniformly denied any effect of the serum on the course of the disease,⁵³ even when an exceptionally high titer antiviral horse serum was used.⁵⁴ The later experiments on prophylaxis by Schultz and Gebhardt,⁵⁵ who raised the level of immune substance in recipient monkeys by passive transfer of neutralizing substances to at least the average level of pooled convalescent human serum, demonstrated that such a procedure allowed 30 per cent survival as contrasted with only 7 per cent in untreated controls. They concluded that the extent of paralysis in poliomyelitis was determined by the general level of natural resistance possessed by neurons (tissue immunity) or by the virulence of the infecting virus strain.

In vitro experiments have been performed recently which show that once virus (vaccinia and Shope fibroma)⁵⁶ has combined with living cells it cannot be neutralized by immune serum. Virus within dead cells can be effectively neutralized. This finding is a disappointing paradox, and, if directly applicable to conditions within the body in poliomyelitis, serum is often too late to preserve susceptible cells unless given before virus-cell union occurs. On the other hand, it is possible that intersegmental spread of virus does take place even after the first paralysis appears. Theoretically, then, it is possible that serum is of value in early paralysis, when end results are compared. There are many difficulties in settling such a question practically. End results have not even been adequately determined after serum has been administered in the preparalytic period in conjunction with adequate orthopedic after-care.

Reference should not be omitted to the results of treatment with convalescent human serum to be found in recent reports. Tebbutt and Helms⁵⁰ observed a lower mortality in the cases treated in the preparalytic stage of 3.3 per cent as contrasted with 11.8 per cent in the untreated controls seen after paralysis was present. Again in this report there was evidence that the preparalytic cases presented milder paralysis and a longer preparalytic period. Jensen⁵⁰ thought that the earlier after the onset of symptoms that treatment was applied, the less the incidence of paralysis. If applied three days or more after the onset of symptoms in the preparalytic period, there was little difference in the percentage developing paralysis. Cowie and his co-workers⁵⁷ have reported no residual paralysis in eighty preparalytic cases treated with both human convalescent serum and transfusions from normal adults. There was but one paralytic case observed in

this series, this rapidly cleared. Symptomatic improvement was noted even in certain paralytic cases. Lastly, Levinson²⁸ has treated 149 preparalytic cases of the seasonal endemic type of poliomyelitis in Chicago during the past four years. He states that the incidence of paralysis has been negligible and that most of the temporary weakness disappeared later. He too has been impressed by the amelioration of symptoms in both the preparalytic group and the paralytic cases presenting smoldering fever or acute recrudescence.

As specific treatment is continued during the next few years, the efficacy of concentrates from antiviral animal serums having advanced neutralizing potency should be evaluated. Titrations of pools of convalescent serums show only a moderate amount of neutralizing antibody. It is possible that tested human convalescent serum or normal human serum of high antibody content would be more effective in practice. Another source of antipoliomyelitis neutralizing substance that may be available for human therapy is human placental extracts.³³ We have recently determined that these preparations contain more neutralizing antibody than the average of convalescent serum pools.

SUMMARY

The peculiar pathogenesis of poliomyelitis as an exclusive disease of the nasopharynx and nervous system with irregular extraneural outflow of virus explains the variability of production of neutralizing antibody in both the experimental disease and the human disease. Blockage of infection at the port of entry by application of chemicals has been recently demonstrated in three widely separated laboratories. This method may have some value in prophylaxis against the disease of man.

The specific virus-neutralizing substance in poliomyelitis is unique in that greater numbers of adults without history of contact or infection possess these substances than convalescents from the disease. The average concentration of immune substance in normal adults is equal to or greater than that carried by convalescents. The importance of an actual attack of poliomyelitis in the production of these substances is minimized by our serologic studies. The role and mechanism of the tissue immunity that exists in this disease has not been elucidated.

Convalescent and other specific serum therapy should be continued, as there is no evidence that it is not of value. On the other hand, symptomatic improvement following the administration of serum is almost universal. There are indications that preparalytic poliomyelitis in man is a naturally milder type of the disease than the cases seen after paralysis is present.

ABSTRACT OF DISCUSSION

DR. SYDNEY O. LEVINSON, Chicago. This paper discloses a comprehensive analysis of a field in which there is much conflicting evidence and thought. It also presents some disconcerting conclusions. It is a pardonable hope that new evidence will provide an answer to some of the unexplained aspects of the disease. However, even though it does not conform with the accepted view, any sincere study must be taken seriously and the evidence examined critically. The authors raise the question whether man ever acquires an effective immunity from an attack. Shouldn't the wording of this question be "when or how often does man acquire an immunity?" The very fact that only a few cases have been reported in the literature emphasizes the rarity of

second attacks in formerly susceptible individuals and justifies the conclusion that a very high percentage are immune. A conclusion is justified unless it is assumed that they were not reexposed, an unlikely supposition in the face of the widespread dissemination of the virus. This is supported by the resistance to reinfection in the experimental animal recovered from a previous infection. The neutralization studies in various stages of poliomyelitis lead the authors to believe, first, that an attack of the disease does not seem to increase the polioviricidal bodies, and, secondly, that there does not seem to be any relation between the presence of these bodies and resistance to susceptibility to an attack. Before one concurs in these opinions, a few commonly accepted facts must be reviewed: 1. Neutralizing substances in monkey serum are found only after an attack of the disease or some immunizing procedure. 2. The relative immunity in adults is accompanied by the greatest frequency of virus neutralizing substances. 3. Limited observations reveal that most infants possess virucidal substances in their serum—undoubtedly a passive transfer from the mother—and the disease is relatively uncommon in infants. 4. Other studies show that the frequency of the disease in different age groups parallels the frequency of antibody deficient serums in these groups. 5. Passive immunization of monkeys tends to protect the animals against the virus. I should like to know whether I gained the correct impression that those patients showing an appreciable amount of polioviricidal substance had no severe or extensive paralysis. How can these two divergent views be reconciled? The answer may lie in the authors' own conclusion that immunity to the disease resides in many factors, tissue and humoral, specific and nonspecific resistance. I believe it would be a mistake to ignore any single factor. I would stress that in this disease, as in others, the amount of the infecting dose may bear a definite influence on the severity of the infection. Whereas in monkeys the infecting dose can be controlled, in man it is an uncertain and indeterminate quantity. It is a factor that must be given due consideration in the analysis of any small group of human cases. This study is valuable in pointing out that polioviricidal substances in the blood stream cannot be taken as the sole criterion of immunity against the disease. Their significance may have been overemphasized in the past, but I question the wisdom of ignoring them in the future. Further investigation may reveal a quantitative relationship in man between polioviricidal substances and resistance to infection. There is urgent need for further work along these lines, because of their importance in the problems of active immunization.

DR. PAUL H. HARMON, Chicago. In the past ten years at least six groups of investigators have at some time or other in the laboratory at least, had a vaccine ready for human application. The deterring fact which prevented these investigators from applying their results to man was that paralysis was produced by the vaccine in from 10 to 20 per cent of experimental monkeys. Only a few of these monkeys were resistant to intracerebral inoculation. Recently Gordon at the University of Chicago has carried out quite an extensive study on vaccination in monkeys. Although he could induce neutralizing substances by virus absorbed to alumina gel very few of these so-called immunized monkeys were resistant to intranasal application of active virus. In fact more than 80 per cent came down with the typical disease following such a test. I think it can be stated that the serum is of some value in the treatment. While I do not have the opportunity of quoting some of the recent reports of treatment of the disease in man I can mention the recent experiments of Schultz at Stanford University who showed that there is definite protection of a small percentage of monkeys by serum given before the virus test. I didn't want to be so pessimistic as to say that no individual ever becomes immune to poliomyelitis. I simply wanted to show the figures to bring up the question and see what others think about this question. It is questionable whether or not the figures are statistically significant. In going over 300 or 400 of our cases of paralysis at the University of Chicago I found two cases in which there had been two separate and distinct attacks of poliomyelitis several years apart. I imagine that if any large orthopedic clinic were to review its cases similar facts would be found. For example, Calkins at the University of Iowa reported two such cases.

UNDULANT FEVER

FURTHER EPIDEMIOLOGIC AND CLINICAL
OBSERVATIONS IN IOWAA V HARDY, MD
NEW YORKC F JORDAN, MD
DES MOINES, IOWAAND
I H BORTS, MD
IOWA CITY

The data comprising this report were accumulated during the period 1930 to 1935 inclusive. The observations include (1) bacteriologic and serologic studies in the Iowa State Hygienic Laboratories, (2) special reports on 705 cases submitted by attending physicians to the Division of Communicable Diseases and Epidemiology, Iowa State Department of Health, (3) personal observations and detailed records of cases presenting unusual clinical features, chiefly patients admitted to the State University Hospitals, and (4) comparative data collected from the different states through the office of the director of the National Institute of Health, Washington, D C. Certain observations in our reported series of 375 cases for the period 1927 to 1929 are also considered. Supplementary information was also drawn from the current literature.

ETIOLOGY

The various strains of *Brucella* isolated from patients in Iowa for the nine years 1927 to 1935 numbered 127 (table 1). All but ten of the organisms were obtained from blood cultures. The other sources were feces (one), urine (two), spinal fluid (two), pleural fluid (one), cervical lymph glands (one), purulent discharge from osteomyelitis (two) and purulent discharge from spondylitis (one). The organism from the spondylitis was a bovine strain, the nine others were porcine. The one melitensis variety was obtained from an infection apparently acquired in Mexico. From this case the bovine variety was simultaneously isolated. In another Iowa case mixed infection with bovine and porcine varieties was demonstrated. In a third individual *Brucella suis* was obtained both from blood culture and from a suppurative osteomyelitis of the wrist. Thus the 127 organisms were obtained from 124 cases.

Comparable cultural studies have been carried out in but few other states. The limited observations clearly indicate markedly different results in different areas. In New York State, for example, a total of fifty-one strains have been isolated and forty-one have been classified. Of the latter, thirty-six (92.7 per cent) were bovine, one (2.4 per cent) was porcine, and two (4.9 per cent) were melitensis. The two melitensis strains were from an imported case and a laboratory infection.

The significance of differences in the prevailing variety of *Brucella* has been more clearly established by the occurrence of two milk-borne epidemics of undulant fever due to the porcine strain. In the Iowa outbreak reported by Beattie and Rice,¹ within a period of three months among approximately 350 regular

patrons of a raw milk dairy there occurred twenty-seven rather severe cases of undulant fever, an attack rate of 7.7 per cent or an annual rate of 30.8 per cent. Similarly, in Connecticut within a period of nine months Horning² observed thirteen cases, with three deaths, in an institution having a population of 386, an annual attack rate of 4.8 per cent. In contrast with these relatively high rates, the average annual attack rate for persons in Iowa using raw milk from dairy herds infected with the bovine strain of *Brucella* has been not over 0.02 per cent. It is apparent that the hazard of exposure to the porcine is far greater than like exposure to the bovine strain. A comparison of the clinical records of the cases giving positive cultures has also shown that those due to the porcine variety almost invariably were particularly protracted and severe. In pathogenicity and infectivity the porcine appears to be similar to the melitensis variety, both differing markedly from the widely disseminated bovine strains. Thus variation in incidence and clinical characteristics, dependent on the distribution of these three strains, is to be expected.

INCIDENCE OF BRUCELLA INFECTIONS

For the United States as a whole the number of reported cases of undulant fever has rather steadily increased from twenty-four in 1925 to 1,897 in 1935 (table 2). According to the data provided by the various state departments of health, reported cases represent about 75 per cent of the number indicated by positive agglutination tests. Thus there have recently been 1.5 reported and about two diagnosed cases of undulant fever per hundred thousand of population annually. The known incidence, however, varies

TABLE 1—The Varieties of *Brucella* Isolated from Cases of Undulant Fever in Iowa

| Variety of <i>Brucella</i> | Number and Percentage of Organisms Isolated | | | | | |
|----------------------------|---|----------|-----------|----------|--------|----------|
| | 1927-1929 | | 1930-1935 | | Total | |
| | Number | Per Cent | Number | Per Cent | Number | Per Cent |
| Porcine | 35 | 71.4 | 53 | 67.9 | 88 | 69.3 |
| Bovine | 14 | 28.6 | 24 | 30.8 | 38 | 29.9 |
| Melitensis | 0 | 0.0 | 1 | 1.3 | 1 | 0.8 |
| Total | 49 | 100.0 | 78 | 100.0 | 127 | 100.0 |

widely. States with two or more officially reported cases per hundred thousand of population are shown in chart 1. It is to be noted that Iowa has the highest attack rate, being closely followed by adjoining states. Judging by the number of cases presenting positive laboratory signs, Iowa actually had a substantially higher rate, 8.7 per hundred thousand of population. Although New York State now has the largest number of reported cases annually, the higher "up-state" attack rate is less than one-half that in Iowa.

For comparative purposes we have calculated the known incidence of undulant fever by regions and have related these to possible determining factors (table 3). The high rate for the West North Central states as compared with other sections is outstanding. It is probable that this difference would be accentuated by more complete reporting of diagnosed cases. The low rates in the largely rural South Central states are also noteworthy.

Data are now available which permit a comparison of the incidence of infection in cattle and in man.

² Horning B. G. Outbreak of Undulant Fever Due to *Brucella* Suis J. A. M. A. 105: 1978-1979 (Dec 14) 1935.

Read before the Section on Practice of Medicine at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

This study was conducted under the joint auspices of the United States Public Health Service, the Iowa State Department of Health, and State Hygienic Laboratories, and the De Lamar Institute of Public Health, Columbia University, New York.

¹ Beattie C. P. and Rice R. M. Undulant Fever Due to *Brucella* of the Porcine Type—*Brucella suis* J. A. M. A. 102: 1670-1674 (May 19) 1934.

July 1 1934 an extensive program for the eradication of bovine infectious abortion was initiated by the federal Department of Agriculture. As a necessary part of this a total of 7400000 agglutination tests have been performed on cattle in nearly a half million herds. The observations should be closely comparable

TABLE 2—*Reported Cases of Undulant Fever (1925-1933)**

| Year | Number of Cases | | | Number of States Reporting Cases |

| Total | 1679 | 1611 | 11426 | |

Data for Iowa based throughout on cases presenting positive agglutination. For 1925 to 1928 the other data were collected by us through special inquiry of all states. For 1929 to 1933 the figures represent cases officially reported to the U. S. Public Health Service as summarized by Ward Glitner (Brucellosis, A Public Health Problem, Memoirs of Agriculture, State College, March 1934) and for 1934 and 1935 the same tabulated from original published reports.

from area to area. The striking feature is the general uniformity in the incidence rather than the differences, as is shown in columns three and four of table 3. Furthermore the highest percentage of positive reactors was in an area (West South Central) with one of the lowest undulant fever rates. In the West North Central states with the highest rate of human infection the incidence of bovine infection was but slightly above the average. Certainly the incidence of Brucella infection in cattle as indicated does not satisfactorily explain the varying rates of attack of undulant fever.

TABLE 3—*Incidence of Undulant Fever in Various Regions of the United States with Factors Possibly Accounting for Variations*

| Region | Cases of Undulant Fever per 100,000 Population Three Year Average | Examination of Cattle | | |
|--------------------|---|---------------------------|--|---|
| | | Rural Population per Cent | Percentage Positive for Brucella Infection | Percentage in Herds with One or More Reactors |
| West North Central | 3.5 | 8.2 | 10.7 | 3.7 |
| Pacific | 2.0 | 22.1 | 7.3 | 43.2 |
| Mountain | 1.7 | 69.6 | 7.5 | 2.5 |
| East North Central | 1.6 | 24.6 | 9.6 | 4.1 |
| Mid Atlantic | 1.5 | 22.3 | 7.3 | 2.9 |
| New England | 1.5 | 22.3 | 10.7 | 0.4 |
| South Atlantic | 1.4 | 6.1 | 7.5 | 49.6 |
| West South Central | 0.7 | 6.1 | 12.2 | 7.6 |
| East South Central | 0.6 | 7.9 | 10.1 | 61.9 |
| Total | 1.6 | 41.5 | 9.5 | 16.6 |

* Total based on what for similarity in the comparison of report for the general average was computed for the three consecutive years 1929 to 1931 with the greatest number of cases. The average for 1925 and 1926 of less than 200 population

The evidence of contagious abortion in hogs is still somewhat uncertain. It is known that the porcine infection is generally distributed as is the bovine. In several European countries, for example, the porcine strain of Brucella has not as yet been encountered in any of our human beings. In the United States the available evidence indicates that infection in hogs is not present in all of the hog-raising areas. In the West North Central states which have the high-

est incidence of undulant fever, over half of the country's hogs are produced. Of all states Iowa has the highest case rate of undulant fever, it also has one-fifth of the country's hogs, and these with a known high incidence of Brucella infection. The porcine strain has been encountered but infrequently in animals other than hogs. Therefore the distribution of porcine Brucella infection coincides with, and probably explains, the disproportionately high incidence of undulant fever in the West North Central states and in Iowa.

The admittedly incomplete evidence derived from animal and human studies seems then to indicate that in the New England, Middle Atlantic, East North Central, South Atlantic and Mountain states the rather uniformly distributed bovine infection is largely responsible for undulant fever. The known case rates in these areas are quite similar. In the West North Central states approximately as many infections are derived from hogs, thus giving a total rate twice that of the aforementioned areas. The low rates of the South Central states may be dependent on less adequate recognition and reporting or on rather widely differing socio-economic and racial factors. The slightly higher than average rate in the Pacific states evidently reflects

Chart 1—Undulant fever in states with the highest incidence three year average calculated as for table 3

the keen interest in this disease on the part of workers in California, and also the known occurrence of the caprine infection in certain parts of this state.

GENERAL EPIDEMIOLOGIC OBSERVATIONS

The distribution of cases by age and sex as shown in chart 2 again indicates that in Iowa undulant fever involves active adult males most heavily. In this study as in that previously reported, slightly more than 75 per cent of our patients were males. The occupational distribution as far as is known is indicated in table 4. The wide variation in the attack rates in different groups is further shown in table 5. The comparatively high rates for men on the farm and the excessive rates for packing house workers strongly emphasize the risk in occupations involving direct contact with livestock and fresh meats. The similarity in rates among women on farms and among other adults not having occupational contact with livestock is added evidence that farm women acquire infection chiefly through the use of raw dairy products.

That there is a definite though not marked variation in seasonal incidence is indicated in table 6. This finding agrees with the early observations of undulant fever on the island of Malta. It is known that there is an increase in the excretion of organisms from animals following the birth of young. It is suggested that the

seasonal variation is accounted for, at least in part, by the heavier exposures during and following the farrowing and calving seasons

Evidence as to sources of infection in individual cases has in this later study rested chiefly on history rather than on examination of animals. Although data are

Chart 2—Undulant fever in Iowa by age and sex 1927-1935

not satisfactory for statistical analysis, the records amply confirm the conclusion that in Iowa undulant fever is acquired from hogs about as frequently as from cattle. Support is also given to our contention that inoculation through the skin not infrequently follows direct contact with the discharges of living animals, including the products of abortion, and especially with the tissues of those recently slaughtered.

CLINICAL FEATURES

The earlier clinical observations of undulant fever in Iowa have been described by Woodward,³ Bierring,⁴ and ourselves.⁵ The data on this later series of cases

and the reported analyses from other states and countries have established the usual clinical characteristics of this disease. Though varying widely in severity and manifestations, there are usually identifying clinical features. The typical onset is gradual but may be abrupt or very insidious. The most constant features of the illness are weakness and elevation of temperature, the most distinctive is profuse sweating. General aching and headache are frequent, pain, moderate or severe, may be localized in the back, neck, joints or abdomen. Sensations of chilliness are common and true rigors not infrequent. Less prominent complaints

include anorexia, constipation, urinary frequency, irritability, insomnia and cough. On observation the patients often have an appearance of well being quite inconsistent with the height of the afternoon temperature. Positive physical manifestations other than a palpable spleen in about one third of the cases are also strikingly lacking. The temperature is usually intermittent, typical undulations are rarely observed but wavelike fluctuations in daily maximums may be noted. Few patients are strictly bedfast, some are ambulatory throughout, but most are "up and down." A normal or low white blood count with a relative increase in

mononuclears is usually found. The diagnosis is ordinarily confirmed by the specific agglutination test, but in a small percentage of cases this test remains negative. Spontaneous and complete recovery in from one to three months is the rule, but one or more relapses are not infrequent. Stubbornly chronic disease occasionally ensues. From 2 to 3 per cent of all cases terminate fatally, usually with manifest complications.

The clinical character and course of generalized Brucella infection are now rather widely known. Recent studies of this disease have emphasized the occurrence of localized Brucella infections, commonly suppurative in character. Their study represents the major recent addition to the clinical knowledge of

undulant fever. Attention is therefore directed to manifestations which have hitherto offered such difficult diagnostic problems.

LOCALIZED BRUCELLA INFECTION

Localization has long been recognized as characteristic of Brucella infection of animals. In guinea-pigs, especially those inoculated with the porcine strain, we have repeatedly observed suppurative lesions, notably arthritis, osteomyelitis, spondylitis, meningitis, orchitis

³ Woodward L. R. J. Iowa State M. Soc. 17:312-317 (Sept.) 1927.
⁴ Bierring W. L. Undulant Fever J. A. M. A. 93:897-901 (Sept. 21) 1929.

and abscesses of the spleen, liver, lymph nodes and other soft tissues. In cattle brucellosis is typically a localized infection, involving the udder, the pregnant uterus and occasionally the joints. In hogs, according to the observations of Thomsen⁶ in Denmark, and Feldman and Olson⁷ in this country, focal lesions are not unusual. The pregnant uterus may be affected. Suppurative or nonsuppurative epididymitis is relatively frequent. Occasionally the testes or seminal vesicles are involved. Destructive bone and joint lesions, meningitis, soft tissue abscesses and tenosynovitis are also encountered. In horses, according to Fitch,⁸ certain rather common suppurative lesions (poll evil and fistulous withers) may be due to *Brucella*.

With such local lesions in animals, the recognition of similar conditions in human beings has not been unexpected. From inflammatory lesions in various sites *Brucella* has been isolated. In many instances the finding of no other organism than this tends to support its etiologic role, in others the causal relationship is still uncertain. In order that bacteriologic procedures effective for the isolation of *Brucella* may be employed more generally in the study of certain medical and surgical conditions we shall enumerate the more common local lesions attributed to *Brucella* infection. Except as indicated, the conditions listed have been observed in Iowa. These localized lesions are as follows:

Skeletal System—Spondylitis. As observed and reported, this has simulated Pott's disease.

Arthritis. This has included relatively acute as well as chronic septic processes, also nonsuppurative lesions.

Osteomyelitis. Various long bones and, in one instance the small bones of the wrist have been involved.

Nervous System—Meningitis and Meningo-Encephalitis. One case closely simulated brain tumor.

Digestive System—Cholecystitis. Amoss⁹ likewise Gilbert and Coleman¹⁰ has isolated *Brucella* from bile aspirated by the duodenal tube or obtained at operation. The organisms have also been obtained in cultures from subacutely and chronically inflamed gallbladders.

Respiratory Organs—Pleurisy with Effusion. In one case *Brucella* was isolated from the pleural fluid by guinea-pig inoculation.

Cardio-vascular System—Endocarditis. This has been a not infrequent observation in undulant fever with complications.

Pericarditis. This occurred in association with endocarditis in one case.

Mycotic Aneurysm. Involvement of the basilar artery was discovered in two cases at autopsy.

Lymphatic System—Adenitis. One case of suppurative cervical adenitis suggesting a tuberculous condition yielded a pure culture of *Brucella*.

Urogenital System—Urinary Tract Involvement. Cases with initial symptoms of cystitis and renal tuberculosis have been diagnosed as undulant fever through isolation of the organism from the urine and positive agglutination test.

Endometritis. The bacteriologic study of aborted fetuses and postabortion uterine discharges has indicated occasional involvement of the pregnant uterus.¹¹

Glandular System—Mastitis. The not infrequent occurrence of this complication in undulant fever gives reason for assuming that the specific infection localizes in breast tissue.

Cutaneous and Subcutaneous Tissues—In several reported cases, chronic subcutaneous abscesses have yielded pure culture of *Brucella*.

In addition to the foregoing, the organisms under consideration have been isolated by different workers also from such places as a pancreatic abscess, an infected dermoid, peritoneal lesions suggestive of miliary tuberculosis, removed tonsils, a pathological appendix and an infected fallopian tube. On the basis of conditions found in animals and clinical observation in human beings, the occurrence of other focal lesions may be suspected, as for example in the lungs or spleen.

There has been wide variation in the clinical types of cases in which these local lesions have occurred but they have been discovered most frequently in chronic infections. In course and character the focal process itself often simulates tuberculosis. Occasionally the local manifestation so overshadows the general symptoms that undulant fever is not suspected. The wide distribution of *Brucella* and the frequency of subclinical infections indicates a more frequent examination for these organisms. Bacteriologic studies of inflammatory processes must be regarded as incomplete if adequate search for *Brucella* is not included.

The prevalence of these localized infections has not yet been determined. Limited observations with a substantial number of positive observations demand that they be more commonly considered in differential diagnosis. Thus far they have been observed more frequently in Iowa than elsewhere, owing, according to present bacteriologic evidence, to their greater frequency in infections with the porcine than with the bovine strains of *Brucella*.

DIAGNOSIS AND THERAPY

With the more general appreciation that the agglutination test remains negative in some cases, other diagnostic aids are receiving more attention. The skin test and the opsonocytaphagic reaction (Huddleson) are being more widely used and accurately interpreted. We feel that the importance of cultural studies must be persistently emphasized. More general adoption of bacteriologic procedures required for the isolation of *Brucella* would increase materially the clinical and epidemiologic knowledge of this disease.

The difficulties in diagnosis of the mild and more chronic forms have repeatedly come to our attention. Evans¹² has recently presented strong evidence that calls for consideration of brucellosis before a too ready acceptance of such diagnoses as neurasthenia or psychoneurosis. The frequency of occurrence of such atypical infections is now being intensively studied in selected localities by the United States Public Health Service.

The difficulty in evaluating any therapeutic procedure in a variable self-limiting disease caused by three different strains of organism is apparent. In our studies we have sought to appraise the specific value of vaccines and brucellin. Large quantities of these preparations have been distributed, but the number and nature of the reports concerning their value permit no definite conclusions. Thus far we can only say that most of the physicians who supplied information spoke approvingly of the response to brucellin therapy. We have not been able to obtain, however, an adequate and controlled series of therapeutic tests. In our opinion the most important therapeutic considerations are early diagnosis, continuous bed rest and general supportive measures.

COMMENT

Epidemiologically, undulant fever is not one disease but a group of three closely related diseases. These are caused by three varieties of *Brucella* which differ as to animal host, mode of dissemination, pathogenicity and probably infectivity for man. Geographically in this country the bovine variety of *Brucella* is widely and rather uniformly distributed, while the porcine and caprine varieties are largely confined to specific localities. On these bases the epidemiologic variations in undulant fever are explainable.

Clinically *Brucella* infection of man presents also a combined picture, that of a generalized infection and of a variety of localized inflammatory lesions. The latter may occur as complications or sequelae of the generalized infection or may appear to be independent processes. The sites of localization are known to be numerous, but the frequency of their occurrence must yet be determined.

CONCLUSIONS

1 During the period 1930 to 1935 inclusive, data were collected on 705 additional cases of undulant fever, giving a total series of 1,080 Iowa cases. This number, according to laboratory observations, represents about two thirds of all cases diagnosed in this state.

2 The porcine variety of *Brucella* was found in a total of eighty-seven, or 70 per cent, of the 124 cases from which the organism was isolated from the blood stream or local lesions.

3 Iowa and the surrounding states have a demonstrably higher incidence of undulant fever than do other areas. Limited evidence indicates that the porcine type of infection is largely limited to these states and accounts for the unusual incidence.

4 The significance of direct contact with livestock and carcasses has been further demonstrated.

5 Recent clinical studies have called attention to a wide variety of localized *Brucella* infections.

6 Blood cultures, skin tests and the opsonocytaphagic reaction are of epidemiologic and clinical importance.

7 Conclusive evidence as to the value of specific therapy has not been obtained.

College of Physicians and Surgeons, New York—Iowa State Department of Health and State Hygienic Laboratories

ABSTRACT OF DISCUSSION

DR. FRED E. ANGLE, Kansas City, Kan. We have just heard a report of the most complete epidemiologic surgery of undulant fever thus far reported in the United States. Dr. Hardy and his co-workers have made a major contribution to medical progress in this study. Their description of the varied symptomatology and the numerous complications immediately places this disease in the category of tuberculosis, syphilis and malignant diseases, in that *Brucella* is capable of attacking any organ. The figures presented would suggest that clinical undulant fever is a comparatively rare condition. This is only partially true because the figures do not include a large number of patients who belong in the subclinical and ambulatory groups. From my experience I am convinced that these are the larger groups. In 2,000 Wassermann serums studied for *Brucella* agglutinins, 26 per cent yielded positive results. Other observers have recorded even higher percentages. Then again, about 6 per cent of acutely ill patients have no agglutinins in the blood but possess either positive *Brucella* cultures, skin tests or cytophagic reactions. May I ask the authors their experience concerning this group? Clinicians are much concerned with the management of these patients. The interpretation of the end results of treatment of patients with brucellosis is most difficult. My experience, and the experience

of many observers both in this country and in Europe, has been most favorable with vaccine therapy. I am convinced that it is the best single therapeutic agent now available. At the Atlantic City session I outlined the treatment of 100 cases observed over a period of seven years. In those patients who do not respond to treatment a careful search may reveal a complicating chronic focal infection. I have had a number of patients who, after the removal of these foci, have promptly recovered. *Brucella* is apparently very toxic to the nervous system. Hence there remains in many patients a residual manifestation usually in the form of neurasthenia or psychoneurosis. I have encountered considerable difficulty in handling this particular phase. No discussion on undulant fever would be complete which did not mention the fact that pasteurization or sterilization of milk and milk products eradicates this source of the disease.

DR. WALTER L. BIERRING, Des Moines, Iowa. This comprehensive study not only represents pioneer investigation of undulant fever but illustrates the value of the correlation of the public health worker and the clinician in furnishing interesting and significant clinical facts. Ten years ago this was regarded a comparatively rare disease and now we have a report of more than 1,000 cases occurring in one state alone. At least three distinct sources of infection exist. Its origin in different animal species, often producing different symptoms, with varying localization, produces a rather unusual clinical picture. Its infection by contact through the unbroken skin is well established and is a contribution by one of the authors. The fact that the porcine type of infection predominates in the series reported is rather significant, although Iowa furnishes one fifth of the hogs of the country, and in this middle section one third of the hogs for the entire country are produced. It is the localization of the inflammations and infections that distinctly complicate the clinical picture. The characteristic clinical syndrome is a weakness, a continuous fever which has an undulating course and a primary sweating period. I believe there is no other form of perspiration that resembles this particular clinical phenomenon. The water just rolls off the patient, the night clothing and bedding requiring changing many times during the night. That it occurs nocturnally is also characteristic. In many respects it resembles the sweating incident to the malarial paroxysm, but it is really more striking. The localization of the disease in the different tissues has brought it prominently under clinical observation. A confusing diagnostic feature is the apparent sense of well being on the part of the patient. The illness can continue for months without the patient appearing very sick. The fact that we are having more milk-borne epidemics is significant, and as these are frequently due to the porcine strain of the *Brucella* organism it becomes difficult to determine to what extent the dairy industry is involved. This offers a further illustration of the danger of contact with diseased tissues, and thus undulant fever is coming to be regarded as an industrial hazard. A specific treatment has not yet been generally accepted, although some virtue is accorded to vaccine therapy. It is interesting to contemplate that practically a new disease has come under observation in this section during the past ten years which taxes our diagnostic ability and thus far has not been very responsive to therapeutic endeavors.

DR. WILLIAM J. KERR, San Francisco. In California we have all three strains of *Brucella* organisms. The porcine strain is found among the hogs from the Middle West brought there for slaughter and consumption. The melitensis strain is brought to us from the Southwestern part of the country and Mexico, seen chiefly in the herds of goats and infecting man through the great consumption of goats' milk in that part of the country. We also have the bovine strain in the cattle. The porcine strain is limited more or less to the workers in slaughterhouses, and the melitensis strain is limited to some extent to the laboratory workers in the institutions where bacteriologic studies are going on.

DR. A. V. HARDY, New York. Dr. Angle asked concerning our experience with the less typical cases not diagnosed by a positive agglutination test. In our study we have given our attention chiefly to those cases in which we were satisfied that there was no question as to the diagnosis of undulant fever and hence we have had but little experience with cases which failed to yield a positive agglutination test. Such as we have had

warrant our emphasizing the diagnostic value of the phagocytic test as described by Huddleson and the skin test. Dr. Angle has also wisely called attention to prevention. The one feature which disturbs us, particularly in Iowa, is that attention is being given at present to the source of infection which gives a less severe type of disease. We feel that before this problem is solved there must be a program of eradication of *Brucella* infection of hogs, such as is now taking place for the eradication of the bovine infection.

THE BLOOD CHANGES IN NORMAL PREGNANCY

AND THEIR RELATION TO THE IRON AND PROTEIN SUPPLIED BY THE DIET

FRANK H. BETHELL, MD

ANN ARBOR, MICH.

Within recent years much has been learned of the physiology of the blood-making organs from the study of the circulating red blood cells. By determinations

Chart 1—A comparison of the frequency distribution of the hemoglobin values obtained on sixty six pregnant women in the last trimester of gestation and on fifty nonpregnant women of the same age range from 18 to 22 years.

of the number of erythrocytes and their size, form and relative content of hemoglobin in the presence of anemia it is often possible to recognize a specific defect in their development and in some instances to supply the deficient factor. Those anemias characterized by small red blood cells and a low color index are generally attributed to a lack of iron, whereas large erythrocytes, carrying more than the usual complement of hemoglobin, are considered to denote anemia of the pernicious group dependent on interference with the maturation of the erythrocytes and due to the lack of a substance found in liver.¹ Although deficiencies other than iron and the factors which make up the liver principle have been suggested as possible causes of impaired blood formation, with the exception of vitamin C² no other dietary lack has been definitely shown to cause anemia in adult human beings.

It is intended in this communication to report the results of blood studies on a group of young women with uncomplicated pregnancies and to discuss some aspects of the relation of diet to the blood in pregnancy. Sixty-six subjects, of whom fifty-four were primiparae, were examined at intervals throughout the last three weeks of gestation. The subjects were unselected except that those with concomitant disease were excluded. During this period they were maintained within an institution and their health and diet were under constant supervision. Among the members of such a group one would not expect to find instances of grave anemia and no such cases were encountered. However, it was thought that analysis of the alterations in the blood commonly found in healthy pregnant women might throw additional light on the etiology of the anemias of pregnancy and provide a basis both for their prevention and for their effective therapy. Erythrocyte counts were made with instruments certified by the U. S. Bureau of Standards. Hemoglobin estimations were carried out by a modified Sahli technique in which 100 per cent is equivalent to 15.8 Gm of hemoglobin per hundred cubic centimeters of blood as determined by the oxygen capacity method. For the hematocrit determinations the Wintrobe tube was used. As an anticoagulant a mixture of 6 parts of ammonium oxalate and 4 parts of potassium oxalate was employed. Two milligrams of the combined dry salts was allowed for each cubic centimeter of blood. In this solution the volume of the erythrocytes is unaltered.³

In such a study, in which deviations from the normal may be slight, the value of a control group is apparent. For this purpose blood examinations were made on fifty nonpregnant young women. The group was made up of student nurses, from 18 to 22 years of age, without evidence of dietary deficiency. It was found that in an appreciable number there occurred a definite decrease in average erythrocyte volume. In some instances in which there existed such a tendency to microcytosis, a history was obtained of excessive menstrual bleeding, and in the others also unrecognized menorrhagia may well have been the cause.⁴ If those nonpregnant subjects with an average erythrocyte volume of less than 85 cubic microns, comprising fourteen

Chart 2—A comparison of the erythrocyte counts obtained from the same subjects as provided in the data shown on chart 1.

members 28 per cent of the total are excluded the values for the control group are: red blood cells range 4,050,000 to 5,280,000; average 4,660,000; hemoglobin range 78 per cent (12.4 Gm) to 97 per cent (15.4 Gm); average 87.5 per cent (13.8 Gm); mean corpuscular

volume, range 85 cubic microns to 96 cubic microns, average 89.1 cubic microns, color index,⁵ range 0.85 to 1.04, average 0.94

Of the pregnant group, sixty, or 90 per cent, showed blood values below the minimum figures for the red blood cell count and hemoglobin as given. The increase in plasma volume known to occur during the latter half of pregnancy accounts in part for the reduction of erythrocytes and hemoglobin. Blood and plasma volume determinations on fifteen of these subjects confirm the conclusions of Dieckmann and Wegner⁶ that, in the

cells, the lowest erythrocyte count that may be explained solely by hydremia is approximately 3,700,000 per cubic millimeter, the minimum hemoglobin is about 70 per cent (11.3 Gm). Values lower than these were found in 70 per cent of the subjects. In table 1 are given the hematologic data obtained from the nonpregnant group and in table 2 are shown the observations in the series of pregnant women. On charts 1, 2 and 3 are plotted the comparative frequency of the hemoglobin values, erythrocyte counts and average erythrocyte volumes of the pregnant and nonpregnant groups. Those cases of

last trimester of pregnancy, an increase in blood volume with relative reduction of red blood cells ordinarily is present and that the volume of the plasma is aug-

⁵ Uncorrected. Corrected color index values may be obtained on data presented in this paper by multiplying by the factor 1.1.
⁶ Dieckmann W. J., and Wegner C. R. The Blood in Normal Pregnancy. Blood and Plasma Volumes. Arch. Int. Med. 53: 71 (Jan) 1934.

pregnancy in which definite anemia existed fell into two distinct groups, approximately equal in number. One, characterized by lowered color index, small red blood cells and an increased percentage of reticulocytes, is readily accounted for by a lack of iron. In the presence of such anemia the bone marrow is reactive, its content of normoblasts is greater than that of the nonanemic person, and through enhancing the availability of iron these nucleated cells will rapidly mature into functional

Chart 3—A comparison of the average erythrocyte volumes obtained from the same subjects as provided in the data shown on charts 1 and 2

erythrocytes. The second group is differentiated by an approximately equivalent reduction of red blood cells and hemoglobin, resulting in a color index nearer unity, by high normal or increased volume of the erythrocytes, and by a reticulocyte percentage below the average normal range. This blood picture is in many respects similar in its distinguishing features to hypoplastic anemia in nonpregnant persons, in whom bone marrow studies reveal an inactive marrow with little evidence of regeneration. Chart 4 illustrates the differentiation of the blood observations in pregnancy into three groups, the first, in which the values are within normal limits or are explainable solely on the basis of increased plasma volume, the second characterized by anemia with low color index and small red blood cells, and the third, in which anemia with normal color index and red blood cells of high normal or definitely increased volume is found.

In the subsequent discussion of these types of blood change in pregnancy data will be presented which, it is felt will place in question a recent contention that the anemias of pregnancy, excepting those due to concomitant disease or loss of blood are limited to a hypochromic type dependent on lack of iron and a pernicious form resulting from interference with the assimilation or utilization of the factors composing the liver principle.

The view that a diet poor in iron and a relative reduction of the capacity of the stomach to secrete hydrochloric acid may together or independently lead during pregnancy to iron deficiency anemia is based on the fact that the infant is dependent on the mother

for the materials required for growth and blood formation before birth as well for a large part of its requirement during the first months of extra-uterine life. It is, however, fallacious to assume that iron is necessarily obtained from the maternal diet at the time it is stored by the fetus.⁹ The total iron content of the new-born child approximates 350 to 400 mg.,¹⁰ or no more than the quantity contained in 1 liter of blood. Considering that the pregnant woman saves from the absence of menstruation over ten percent from one third to one half of this amount of blood the net iron loss is no more than would be removed through serving as donor for a single moderate sized blood transfusion. The reserves of blood and of blood

building materials possessed by the healthy person without a tendency toward anemia are adequate to replace such a loss without demonstrable effect on the blood level.

In order to check the validity of this reasoning, a continuous determination of the iron exchange was carried out in the hospital on a healthy young woman throughout the last sixty-three days of her pregnancy

Chart 4—Classification of the blood values of sixty-six pregnant women according to the type of bone marrow reaction to the demands of pregnancy

and the first twelve days after delivery.¹¹ A number of significant iron balance studies on pregnant women have been reported by Coons¹² but her conclusions based on short period observations are open to objection that even though the diet is constant the

put of iron fluctuates widely from week to week. Moreover, since the subjects of her investigations were not proved to have normal blood values in respect to hemoglobin level, erythrocyte count and average erythrocyte size, their dietary requirements for blood formation were not necessarily physiologic.

The subject of the present study received a uniform diet supplying 7.1 mg of iron daily. Supplementary vitamins A, B, D and C were given, and the total daily

Chart 5—The iron exchange and the blood values of a healthy woman during the latter months of pregnancy

protein approximated 80 Gm supplied chiefly by milk, eggs and canned salmon. The combined urine and stool daily iron output, averaged for the total time of observation, equaled exactly the intake, although marked variations occurred in successive six day periods. The average daily intake and output of copper were respectively 2.20 and 2.15 mg daily. In spite of a relatively low iron and copper content of the diet and practically no retention of either element during the last months of gestation, the blood values were maintained at levels distinctly above the average in pregnancy (chart 5). The blood of the infant likewise showed high normal values. It is significant that the habitual diet of this subject, before coming under observation, lacked meat and eggs with a consequent low iron and copper content. She was, however, accustomed to drinking a generous quantity of milk. It is also of interest that gastric analysis performed on two occasions revealed absence of free acid after alcohol stimulation, although hydrochloric acid was present in considerable amount after the subcutaneous injection of histamine.

During pregnancy there commonly occurs a reduction in the quantity of hydrochloric acid secreted by the stomach in response to physiologic stimuli.¹² Such relative hypochlorhydria has been considered an important factor in the development of the iron deficiency anemia of pregnant women,¹³ since it has been shown that iron is more readily absorbed from an acid than from an alkaline medium.¹⁴ However, the data presented in table 3 demonstrate no relationship between the amount of gastric hydrochloric acid secreted in

response to alcohol stimulation and the level of the blood count. Although limited in number, these observations suggest that temporary reduction of the gastric acidity is not a direct cause of lowered blood values in pregnancy.

The explanation of the occurrence of hypochromic anemia in pregnant women is not to be found primarily in the circumstances incident to gestation but should be sought in the status of the hematopoietic mechanism prior to conception. In the series of cases under discussion the percentage of pregnant women developing definite anemia of the iron deficiency type equals almost exactly that of the nonpregnant subjects showing a tendency to such anemia as evidenced by small red blood cells. These results may be presumed to indicate depletion of the iron reserves, whether caused by excessive blood loss, repeated childbirths or defective assimilation of the metal, thus rendering such a woman less able to meet the moderate demands of pregnancy. Consequently, the routine administration of iron during gestation serves less of a prophylactic purpose than as a corrective measure and is effective in those cases in which predisposition to hypochromic anemia already exists. Although no disadvantage is known to attend the indiscriminate use of iron in pregnancy, many instances are encountered in which its administration fails either to correct or to prevent anemia. Illustrations of such failure of response to iron therapy are provided in chart 6. Such anemia is not of the iron deficiency type and it may be differentiated from it by simple diagnostic procedures. It would seem to be distinctly advisable to give effective doses of an inorganic

Chart 6—The effect of the administration of reduced iron on the hemoglobin level of pregnant women with hypochromic anemia and its lack of effect in cases of anemia with normal color index and normal or increased average erythrocyte volume

iron preparation to all pregnant women regardless of the actual level of the hemoglobin, if an accurate erythrocyte count and hemoglobin determination by a standardized method reveal a low color index or if the erythrocyte count and hematocrit determination give an average red blood cell volume of less than 85 cubic microns.

Those subjects comprising the second group, in whom the anemia fails to respond to iron, were frequently

found to possess red blood cells of relatively large volume. However, unlike the macrocytes of pernicious anemia, their average diameter approximates the normal value. It may be inferred that these erythrocytes were less biconcave than the normal cell, and consequently the phenomenon may more accurately be defined as spherocytosis than as macrocytosis.¹⁵ Recent studies, summarized on chart 7, have shown that there is an

Chart 7—The inverse relation between the level of the serum albumin and the average volume of the erythrocytes observed on pregnant women without iron deficiency anemia.

inverse relation between the average volume of the erythrocytes and the level of the serum albumin in pregnancy, except in cases of iron deficiency anemia in which true microcytosis occurs. Since the relation between the cell volume and the colloid osmotic pressure was found to be less definite it is probable that the swelling of the erythrocytes cannot be explained solely on an osmotic basis.¹⁶

It was observed that patients with this type of blood change and anemia of hypoplastic nature frequently underwent improvement after admission to the hospital, where they received a better diet than that to which they had been accustomed, particularly in respect to the protein supplied. The protein content of the University Hospital general diet averages approximately 65 Gm daily. Supplementing this diet by 1,000 cc of milk daily has led to correction of the anemia, restoration of the average erythrocyte volume to normal, and increase in the serum albumin. It is believed that the beneficial effects of the milk supplement may be attributed to its supply of about 33 Gm additional protein daily of high biologic value. Charts 8 and 9 depict the responses of the blood to iron and protein, respectively, on the part of two pregnant women with contrasting types of anemia.

With the collaboration of Miss Jean Kyer, studies have been made of the effects of pregnancy on the blood of albino rats maintained on diets supplying variable amounts of iron and protein. The details of this work will be published in a separate communication. Rats receiving a diet low in iron developed a slight degree of anemia characterized by hypochromia and microcytosis, but in this connection it should be emphasized that the iron requirement of rats during pregnancy is relatively much greater than that of human beings

because of the large size of the litter and the rapid course of gestation. On the other hand, a low protein diet, containing an excess of iron, led to severe anemia with red blood cells of increased volume. Rats receiving an abundance of protein and a moderate supply of iron showed an actual increase during pregnancy of the erythrocyte count and hemoglobin value, without alteration of erythrocyte size.

CONCLUSIONS

1 Studies were made of the blood of sixty-six healthy young women during the last trimester of pregnancy, and similar observations were obtained from fifty healthy nonpregnant women of the same age group. In 70 per cent of the pregnant subjects the blood values were too low to be accounted for solely by increased plasma volume with consequent blood dilution.

2 Anemia in pregnancy is commonly due either to preexisting iron depletion or to an inadequate intake of protein of high biologic value during gestation. Rarely it is of the pernicious type amenable to liver or stomach therapy.

3 A lack of iron may be recognized before the development of actual anemia by the presence of a lowered color index or of red blood cells of less than normal size. In such cases the administration of an inorganic iron preparation in adequate dosage is indicated.

4 Anemia dependent on protein deficiency, characterized by a normal color index and by red blood cells of normal or increased volume, may be prevented or corrected by a suitable diet.

ABSTRACT OF DISCUSSION

DR R. B. SCHUTZ, Kansas City, Mo. A study of deficiency diseases in pregnancy is of extraordinary interest, but in searching for etiology one is easily driven to philosophy. Why is it that the so-called physiologic changes in pregnancy so often become exaggerated and produce vicious types of disease? Or

Chart 8—The effect of the administration of reduced iron to a patient with hypochromic and microcytic anemia of pregnancy.

wonders whether primitive women suffered the deficiencies that modern women have. Are we proving that after all the food is a parasite taking to itself what it will regardless of the source? It is important in the problem of the anemia of pregnancy to consider their possible relation to disorders of the endocrine system. As yet too little is understood of the relationship of the endocrine glands and the bone marrow. There is no doubt of the profound endocrine changes associated with pregnancy, and as a common source for study it might be well to study the bone marrow in pregnancy.

¹⁶ F. C. P., L. E. S., and P. H. S., Similarities in the Changes of the Blood in the First Half of Pregnancy and in Erythrocytosis in the First Half of Pregnancy. *Am. J. Clin. Chem.* March 1934.

Dr Bethell mentioned bone marrow studies in his paper but did not specify whether they were made in cases of anemia of pregnancy or in nonpregnant women. I should like to make the suggestion, although I shudder when I think of the implications, that in order to obtain a better understanding of this problem we begin to do marrow biopsies in pregnancy. I, for one, would hesitate to start, but I hope there is some one sufficiently courageous. The progressive nature of these anemias to an almost typical pernicious type suggests that studies in pregnancy might have far reaching effects. There have been a number of papers written on the subject, and each seems to bring us a little closer to the solution. I am particularly interested today in what was said about protein in the diet in its relationship to anemia.

DR. ADOLPH SACHS, Omaha. I made a rather exhaustive study of the copper and iron in twenty-five normal pregnant women taken at random. As is well known, there is a reciprocal relationship between copper and iron in the whole blood. The copper probably acts as a catalyzer. In normal women—nonpregnant women—there is an average of 45 mg of iron per hundred cubic centimeters of whole blood and an average of 131 micrograms of copper. As the iron goes down the copper goes up. I at no time have found a copper deficiency. The pregnant woman has below the average of iron in her blood. She will average 40 mg of iron per hundred cubic centimeters instead of 45 mg. She will average 195 micrograms of copper, whereas the normal woman averages 131. Half of this copper is to be carried over to the fetal liver for future

Chart 9—The effect of a high protein diet (95 Gm daily) given to a patient with anemia characterized by normal color index and increased average erythrocyte volume.

supply, because in the fetus there is only 82 micrograms per hundred cubic centimeters of cord blood, and there is an excess of iron averaging about 50 mg per hundred cubic centimeters of cord blood. So it is the mother who is carrying the copper over to the fetal storehouse. In the anemia of pregnancy there are two types, the physiologic type and the true anemia. Whenever there is any anemia, the copper will rise and the iron will go down. The same occurs with a pregnant woman, but she has a double purpose for carrying this copper. The true anemia will produce a hypoferronemia and in addition she has her hypercupremia not only to supply the fetal storage but to mobilize copper for the mother's anemia. I have found that the polycythemia of the infant is not due to anoxemia, as was once thought, because the work has been done on cesarean sections under local anesthesia and rapid delivery; however, the polycythemia still exists with a low copper and a high cord blood iron.

DR. FRANK H. BETHELL, Ann Arbor, Mich. The nature of the interference with blood formation in pregnancy occasioned by deficient protein is not well understood. In the presence of lowered plasma albumin the red blood cells tend to become more spherical, with coincident reduction of their number. The possible bearing on hematopoiesis of derangements of function of the endocrine glands is a subject on which little information exists in either the pregnant or the nonpregnant state. Also worthy of further investigation is the relationship of other mineral constituents of the diet, particularly calcium, both to the assimilation and to the utilization of iron. The work of Dr

Sachs and his colleagues on the reciprocal relationship of the iron and copper content of the blood has provided an explanation of our failure to obtain better results from the administration of copper as a supplement to iron than from iron medication alone in the treatment of the iron deficiency anemias.

DISAPPEARANCE OF THE PHYSICAL SIGNS OF RHEUMATIC HEART DISEASE

EDWARD F. BLAND, MD

T. DUCKETT JONES, MD

AND

PAUL D. WHITE, MD

BOSTON

We are presenting in this report observations on the disappearance of certain physical signs considered characteristic of rheumatic involvement of the heart. The appearance of so-called organic murmurs during the course of rheumatic fever or chorea is generally accepted as evidence of valve injury. Cardiac enlargement when present lends further support to the clinical impression of extensive involvement of the heart. It has been shown recently that dilatation alone may be an important factor during severe rheumatic infection responsible in some instances for cardiac murmurs, especially for a mid-diastolic rumbling sound at the cardiac apex previously considered indicative of mitral stenosis¹. It is evident, however, from both clinical observation and postmortem study that with demonstrable involvement of the heart during rheumatic fever the mitral valve rarely escapes and, furthermore, the aortic cusps are injured in over half the cases. The persistence of characteristic murmurs after subsidence of the infection constitutes, therefore, our most reliable indication of residual valve injury.

It is well known that the signs of valvular disease which appear during rheumatic fever or later usually persist throughout life and often progress during subsequent years. It is less well known, however, that these signs of cardiac involvement may occasionally regress and ultimately disappear. Isolated instances have been observed and commented on by numerous clinicians but accurate data on the incidence and subsequent course of this fortunate group have not been recorded. Coombs² has expressed the opinion that in as many as 31 per cent the signs of rheumatic heart disease once present may later disappear. To us this figure appears too high and his published data as to both the original condition and the subsequent observations are inadequate for critical analysis. A comprehensive study of rheumatic infection and heart disease in progress now for a number of years has presented an opportunity to investigate further this occasionally observed but imperfectly understood aspect of the course of rheumatic heart disease in young people.

CLINICAL MATERIAL

The material dealt with in this report has been assembled from two sources. Since 1920 approximately 1,500 children and adolescents with rheumatic

From the House of the Good Samaritan and the Massachusetts General Hospital.

The expenses of this study have been defrayed by a grant from the Commonwealth Fund.

fever or chorea have received prolonged bed care and intensive study at the House of the Good Samaritan during the active stage of their disease. The average period of hospitalization has been from three to four months, and not infrequently as long as from one to two years. Furthermore, a unique aspect of the study has been the subsequent observation at frequent

18 years, and hence the decade during which rheumatic infection is most prevalent and most damaging to the heart. Only that portion of this extensive study relevant to the regression and disappearance of the physical signs of rheumatic heart disease has been included in this communication.

In table 2 we have indicated the general course of events for the group of 1,000 patients with clinical evidence of heart disease during the first ten year period. It is to be noted first that 272 (27 per cent) are dead. A recrudescence of rheumatic infection was directly responsible for the fatal issue in the majority. We are interested primarily, however, in the group of eighty-three patients in whom all evidence of valvular disease subsided.

DIAGNOSTIC CRITERIA

For the purpose of this and comparable future studies we believe it essential to define clearly the diagnostic criteria accepted in this report as clinical evidence of rheumatic valvular disease of the heart. A number of borderline cases have been excluded.

I Etiology—All patients in this group of eighty-three in whom the physical signs of rheumatic heart disease later subsided had at the time of hospitalization, or within the recent past, clinical manifestation generally considered rheumatic in origin. Frequent among these were joint pains, chorea, nodules, nose bleeds, erythema multiforme associated with unexplained poor health, fever and laboratory evidence of low grade infection.

II Structure—A. The diagnosis of valve defects is based on the following physical signs and the clinical impression of a staff of experienced observers especially interested in cardiovascular disease.

1 Organic mitral regurgitation was considered present if after the subsidence of active infection and without other important cause of ill health there remained

intervals of the majority of this large group. We ourselves have done the greater portion of this follow-up study. Invaluable aid has been rendered by the medical and social service departments of the general hospitals in Boston. From this large group of 1,500 only those patients have been included (1,184 in number) in whom the subsequent follow up has been sufficiently long to yield useful data. The average duration of this subsequent observation from the onset

M.E., Moderate to marked enlargement

of rheumatic infection to the present time has been approximately ten years. A smaller and similar age group from the Massachusetts General Hospital also followed by us has been included primarily for comparison but for our purpose the two groups are in all respects comparable. Pertinent details relating to these two groups are summarized in table 1. It is to be emphasized that the data represent observations on the course of rheumatic infection and its cardiac complication during the first decade after the onset in young people only and is not necessarily indicative of the course of rheumatic heart disease in later life. The average age for the group at the time of onset of rheumatic infection or chorea was 8 years, so that the study embraces essentially the period from 8 to

a loud systolic murmur heard with maximal intensity at the cardiac apex which was uninfluenced significantly by respiration or change in position of the patient. We recognize that this represents perhaps a controversial group and that the loud and persistent murmur present in these patients may be due occasionally to other unrecognized factors. However we are convinced from clinical and postmortem study that structural alteration in the mitral cusps is directly responsible for the cardiac murmur in the majority of this group.

2 Mitral regurgitation and stenosis were diagnosed clinically in the presence of a blowing systolic and low pitched murmur or rumble in mid or late diastole at the cardiac apex. Attention has been called to the frequent discrepancy between the clinical diagnosis

the extent of structural alteration found post mortem in many of these patients, especially as regards the interpretation of the diastolic rumbling sound as indicative of actual narrowing of the mitral orifice. With this reservation we have retained the term "mitral regurgitation and stenosis" for this group. No instance of "pure" mitral stenosis of the so-called adult type with a harsh late diastolic murmur ending with crescendo in a slapping first sound with subsequent disappearance was encountered in these children.

3 Aortic regurgitation was considered present if there was audible an early diastolic murmur best heard either at the aortic or at the pulmonic area or down the left side of the sternum. In each of the relatively few instances with subsequent regression in which this valve defect was diagnosed, the murmur was soft and

Fig 1—Teleroentgenogram (at 7 feet) showing marked cardiac enlargement (dilatation) during severe rheumatic fever in a boy aged 7 years. A loud apical systolic murmur was present at this time.

of slight intensity. No instance of free aortic regurgitation with subsequent disappearance has been encountered.

B Cardiac size is considered arbitrarily under three divisions:

1 No enlargement is considered present if the point of maximal intensity of the cardiac apex and the left border of dullness are located either in or within the midclavicular line in the fourth or fifth interspace.

2 Slight enlargement is considered present if the apex impulse and the left border of cardiac dullness are from 1 to 2 cm outside the midclavicular line in the fifth intercostal space.

3 Moderate to marked enlargement is diagnosed if the apex impulse and the left border of cardiac dullness are more than 2 cm beyond the midclavicular line.

Many of the patients have been examined by x-ray both at the time when rheumatic heart disease was considered present and later when the physical signs of valvular disease had subsided. Discrepancy between the estimate of cardiac size made in this way and that made from physical examination has been infrequent.

DISAPPEARANCE OF PHYSICAL SIGNS

In table 3 we have assembled and summarized the pertinent data relating to the subsequent disappearance of physical signs considered indicative of rheumatic heart disease in this group of eighty-three patients. We have arranged these patients in four major groups according to the cardiac murmurs on which the diagnosis of valvular disease was based. In the second section of the table we have indicated the clinical estimate of the size of the heart together with the results of x-ray examinations when such were available. Finally, in the division of the table on the right we have summarized the present status of this group, all of whom on physical examination show no clinical evidence of residual cardiac disease. A review of the physical signs at the time rheumatic heart disease was

originally diagnosed reveals that uncomplicated mitral regurgitation was present in twenty-six patients. In approximately half of these (fourteen) there was enlargement of the heart. In fifty-three patients mitral stenosis and regurgitation were considered present and in two thirds of these there was cardiac enlargement. In addition to mitral regurgitation and stenosis there was also slight aortic regurgitation in three others, all of whom had enlargement of the heart. Finally, in one additional patient without cardiac enlargement there were present the murmurs of mitral regurgitation and slight aortic regurgitation.

It is to be noted that of the total group of eighty-three patients previously considered to have rheumatic valvular disease no murmurs now can be elicited in any position or after exercise in fifty-three patients. In thirty instances, however, there is still audible a faint and inconstant systolic blow best heard in the majority in the pulmonary area and considered functional in origin. There remain no diastolic murmurs in any instance. The size of the heart on physical examination is now within the normal range in each patient, but, as indicated in the table, fluoroscopic examination reveals a borderline and suspicious prominence in the vicinity of the pulmonary conus in four patients of the group of thirty-eight who have recently had x-ray examinations. In two others the heart remains at full size in the region of the left ventricle. Reproductions of the x-ray films of one of the latter patients is shown in the accompanying illustrations and show in figure 1 well marked enlargement of the heart during active rheumatic infection. Figure 2, taken one year later after all clinical evidence of heart disease had subsided, shows the heart to be considerably smaller but still full sized. A loud apical systolic murmur previously present has completely disappeared. No attempt has been made in this study to apply the "angle of clearance" tests during fluoroscopy recently discussed by Wilson³ and her associates.

Some indication of the course of events and the manner of disappearance of these murmurs is shown in table 4. In those patients who were considered to have mitral valve involvement on the basis of apical systolic and diastolic murmurs, the diastolic murmur was invariably the first to disappear. Occasionally this apical diastolic rumble subsided within a few months after the onset of rheumatic infection, during the period while the patient was convalescing and was still under observation in the hospital. This further supports our previously expressed opinion that cardiac dilatation during active rheumatic infection is often a significant factor responsible for this murmur as well as for a blowing systolic murmur at the cardiac

Fig 2—Teleroentgenogram (at 7 feet) showing a remarkable diminution in size of the cardiac shadow in the same patient as in figure 1 one year later after all evidence of active infection had subsided. The heart is now clinically normal and no murmurs are audible.

apex Therefore in those instances, of which there were sixteen, in which the physical signs of apparent valvular disease subsided within the first year, we suspect that in the majority cardiac dilatation alone was primarily responsible for the murmurs. The usual sequence of events, however, has been a more gradual regression over a period of years. The ultimate disappearance has occurred most frequently during the first five years, as is shown in table 4. An unexpected

TABLE 4—Duration of Physical Signs of Rheumatic Heart Disease (Eighty-Three Cases)

| Years Cases | 1-2 | 3-4 | 5-6 | 7-8 | 9-10 | 10+ | ? |
|----------------|-----|-----|-----|-----|------|-----|---|
| | 18 | 2 | 17 | 11 | 5 | 1 | 6 |

accident provided us a unique opportunity to study post mortem the valve cusps in a single patient of this group in whom we had observed the gradual and complete disappearance of the physical signs of rheumatic valvular disease known to have been present six years before subsidence. We record herewith pertinent details of this important case.

REPORT OF CASE

C. C., a girl, aged 13 years, had scarlet fever, which was followed promptly by rheumatic fever in 1927. At the Boston City Hospital a diagnosis of rheumatic heart disease was made and she was transferred to the House of the Good Samaritan for convalescence. Physical examination on entry and throughout her four months stay showed the heart to be slightly enlarged with the apex impulse and the left border of cardiac dullness in the fifth interspace 1 cm. outside the midclavicular line. Maximal at the apex were audible a loud blowing systolic murmur and a low pitched mid-diastolic murmur. Along the left sternal border was also heard a definite soft blowing diastolic murmur immediately after the second sound. A diagnosis of mitral regurgitation and stenosis and slight aortic regurgitation was made. She remained well after leaving the hospital and reported at frequent intervals for follow-up examination. In 1930 (three years after the onset) the aortic diastolic murmur had disappeared. In 1933 (six years after the onset) the mitral diastolic rumble subsided, leaving a moderately loud apical systolic murmur and third sound. In 1934 and 1935 there remained only an insignificant and distant apical systolic murmur which disappeared completely with inspiration. Fluoroscopic examination at this time showed the heart to be normal in size, in shape and in pulsations with no evidence of abnormal auricular or pulmonary conus prominence in the oblique view. She continued well, but in October 1935, four months after the last examination the patient died unexpectedly in a dentist's chair immediately after the extraction of a tooth under gas-oxygen anesthesia. Post-mortem examination (medicolegal) revealed slight but definite scarring of the mitral cusps of sufficient degree to warrant the pathologic diagnosis on macroscopic examination of a 'healed' rheumatic endocarditis. There remained, however, no important deformity and furthermore, there was no detectable scarring of the aortic cusps. The heart weighed 275 Gm., a figure within the normal range for this age (20 years). The cause of the sudden death remains obscure.

The explanation for the early blowing basal diastolic murmur originally present in this patient is not clear. It is possible that a healed scar on the aortic cusps may have been so slight as to escape notice post mortem. The previous injury to the mitral cusps had healed in such a fashion that the residual scar was of slight degree and insufficient to produce characteristic murmurs of mitral valve disease during the two years prior to this patient's death.

CONCLUSION

In this series of 1,000 young patients with the physical signs of valvular disease of the heart who have been examined at frequent intervals during the first

decade after the onset of rheumatic infection, we have observed a regression in these physical signs in a considerable number and the total disappearance of all clinical evidence of heart disease in eighty-three instances. In a few, cardiac dilatation during the stage of active rheumatism may have been responsible for the murmurs usually considered characteristic of valvular disease. If this is true, it is the probable explanation for the relatively rapid disappearance of the cardiac murmurs in a small number during the first year.

It is our belief, however, that the majority of this group of eighty-three patients had injury of the valve cusps (usually the mitral) at the time of rheumatic fever. That it was of minimal degree in each instance seems most likely, so that the residual scarring has produced no significant deformity or characteristic murmurs. It is of interest that, although cardiac enlargement (dilatation and possibly pericarditis) was in some cases of extreme degree, it has in each instance subsided. Six borderline cases (by x-ray examination) remain questionable.

It is to be noted that we have not observed in a single instance in these children the disappearance of either (1) a very loud diastolic murmur ending in a loud crescendo presystolic roll or (2) a loud aortic diastolic murmur and the peripheral circulatory signs of free aortic regurgitation.

It will be of considerable interest and importance to follow further this group of eighty-three patients (one is now dead) to determine whether in some at least the signs of valvular disease (especially mitral stenosis) may later and insidiously reappear without the recurrence of clinically recognizable rheumatic infection. Although as yet the data are inconclusive, we have evidence from a group of patients with so-called potential rheumatic heart disease which suggests that later mitral stenosis may slowly develop in a few instances.

CONCLUSIONS

From a follow-up study of 1,000 children and adolescents with rheumatic heart disease it has been shown that

1. Certain physical signs considered characteristic of valvular disease may occasionally regress and ultimately disappear.

2. This favorable sequence of events was observed during the course of ten years in eighty-three instances (83 per cent).

3. Postmortem observations following an unexpected accident have been recorded in one case.

4. It is probable that in the majority minimal scarring without significant valve deformity remains notwithstanding the absence of characteristic murmurs. Cardiac dilatation alone is occasionally responsible for the physical signs of valvular disease during active rheumatic infection.

25 Binney Street

ABSTRACT OF DISCUSSION

DR. FRED M. SMITH, Iowa City. Regression of cardiac signs in rheumatic heart disease, particularly cardiac enlargement, is rather common and occasionally a striking change in this respect is noted. The disappearance of what appears to be a well established murmur, however, is a feature that has not been emphasized. I am inclined to believe that the murmur disappears far more often than is suspected in the case in which there is a minimal involvement of the heart. It is worth bearing in mind that there are two factors primarily responsible for the cardiac disability in this form of heart disease: the invasion of the myocardium by the rheumatic process

second, the mechanical handicap imposed by the diseased valves. These observations bring up an important point with reference to the pathology. Prior to a few years ago attention was focused on the endocardial lesions. It is now known that this is one of the expressions of a valvulitis and that all structures of the heart may be involved to a varying extent by the infection. In those who die within a few months or a few years from rheumatic heart disease, the damage to the myocardium is the outstanding feature. In those who live twenty or thirty years, however, the damage to the myocardium may be minimal, whereas the involvement of the valve structures is the conspicuous feature. Between these extremes the two factors involvement of the myocardium and the mechanical handicap imposed by the damaged valve structures participate to a varying extent in the production of the cardiac disability. It is doubtful that the murmur ever completely disappears following a significant involvement of the valves. In most of the cases cited by the authors it is probable that the disappearance of the infection from the myocardium was for the most part responsible for the changes observed in the physical signs.

DR. P. T. BOHAN, Kansas City, Mo. The interesting question brought up in this paper is why patients develop a diastolic murmur at the apex without any definite narrowing of the mitral orifice. The suggestion made by the authors that this murmur may be due to a loss of tone or disturbed function of the myocardium seems plausible to me. A patient seen recently has a direct bearing on this point. A girl of 16, suffering from a very high grade gonorrheal arthritis, two months before her death developed a very distinct middiastolic murmur at the apex, and the diagnosis of mitral stenosis was made. At autopsy we were very much surprised to find there was not the slightest sign of stenosis of the mitral valves, nothing but some vegetations along the valve margins, rather typical of rheumatic endocarditis, and in the aorta there was an ulcer about 1 cm. in diameter. Direct smears from this ulcer showed gonococci. There was only moderate dilatation of the heart in this case. At the time of the autopsy it was thought that a probable cause for the apical diastolic murmur was a relative stenosis of the orifice due to an edema, but histologic studies of the myocardium showed granulomatous foci, interpreted by the pathologist Dr. F. C. Helwig as probably fibrosing Aschoff bodies. The autopsy in this case tended to support the suggestion made by the authors that a diastolic murmur at the apex may be due to disturbed function of the myocardium. Another point I should like to emphasize is that the authors made the diagnosis of mitral regurgitation rather frequently in these children. This reminds us of the fact that we should not get too scientific in minimizing the importance of a systolic murmur at the apex. For a number of years following an attack of endocarditis the only evidence, if any, of mitral disease may be a systolic murmur at the apex with or without demonstrable cardiac hypertrophy. The sclerosing process that gives rise to a stenosis is very slow. I have often felt that many of the patients seen at middle life or older with a pure mitral stenosis suffered in their youth from a mild attack of endocarditis that had gone unrecognized. It is to be hoped that few, if any, of the eighty-three cases that the authors observed for ten years with negative results will show up later in life with a pure mitral stenosis.

DR. WILLIAM J. KERR, San Francisco. I would suggest that there may be a type of murmur which has not, up to this time, been recognized. I believe that the diastolic murmur which the authors have discussed this morning, occurring in the acute stages of rheumatic fever and found in a number of other conditions such as severe anemias and leukemias, is due to relative insufficiency of the pulmonary valve. In these patients, if one listens very carefully near the apex of the heart, one may be able to recognize frequently a presystolic element, if the rate is not too fast, as well as a middiastolic element. It is my opinion that this murmur is analogous to the Austin Flint murmur in aortic insufficiency but in this instance is associated with pulmonary insufficiency. It is a murmur of low intensity because of the low pressure in the pulmonary circuit, which is further reduced during the failure of the heart. If one listens over the base of the heart in these patients, one will find on the pulmonary side a very early short diastolic

murmur, which is like the Graham Steell murmur of pulmonary valvular insufficiency. I would suggest, therefore, that in those patients with a systolic murmur at the apex due to relative mitral insufficiency one should expect evidence of failure of the right side of the heart also. The enlargement of the right side of the heart shown in the illustrations by the authors is to be expected in these patients. Clinical experience suggests that the ventricular myocardium is generally involved. Further study will, I am sure, confirm my opinion that dilatation of the pulmonary valve is the origin of the diastolic and presystolic murmurs arising early in rheumatic fever.

DR. T. DUCKETT JONES, Boston. It is to be regretted that so considerable an amount of the reported study is concerned with murmurs and their interpretation. This is especially true since one may with relative ease care for rheumatic fever and heart disease subjects without many of the older ideas of the significance of murmurs being considered. In this connection I should like to stress one point. In caring for patients with rheumatic fever and heart disease the important pertinent features are relative to whether or not there is active rheumatic fever or active carditis in progress. The determination of this is important from the point of view of prognosis as well as of therapy. As pointed out in this study, the first five or six years of the life cycle of rheumatic fever in the young subject will usually determine his prognosis. If he escapes repeated recurrences of the disease or the development of severe heart disease there is every chance of his remaining well physically. It is heartening that such an experience is true so often in a large series of patients followed for a period of years. I wish therefore to make the plea to physicians that the important factors in determining the therapy and prognosis in subjects with rheumatic fever and heart disease is the determination of the active disease process rather than the presence or absence of any particular cardiac murmurs.

EFFECTS OF STANDARD, PROTAMINE AND CRYSTALLINE INSULIN ON BLOOD SUGAR LEVELS

HUGO A. FREUND, M.D.

AND

SIDNEY ADLER, M.D.

Chief of Department of Internal Medicine and Research Resident
Respectively Harper Hospital
DETROIT

During the past few months there have been several reports on the use of protamine insulin in the treatment of diabetes mellitus. The first reports were those of Hagedorn and his co-workers¹ from Copenhagen, who combined insulin with a monoproamine which was buffered at pH 7.3, approximating that of blood serum. Root, White, Marble and Stotz² reported their clinical results at the same time. More recently Lawrence and Archer,³ Kerr, Best, Campbell and Fletcher⁴ and Sprague and Blum and their associates⁵ have reported essentially the same results.

Previously cited investigators stated that the chief advantages of protamine insulin lie in the following observations:

- 1 The rate of absorption was slower than with regular insulin.
- 2 Its action on reducing the blood sugar level was more prolonged than the action of standard insulin.

Studies carried out by grant from A. Wineman Fund.

From the Department of Internal Medicine, Harper Hospital.

3 Hypoglycemic reactions occurred less frequently and were milder in character when they did occur

4 Marked fluctuations of the blood sugar level commonly obtained with the use of standard insulin were diminished

5 Reduction in the number of doses could be made with most patients by using protamine insulin as the evening dose

6 A single or double dose of protamine insulin administered daily could be used in some cases to replace two or three doses of standard insulin

The noted disadvantages of protamine insulin were

1 The instability of the compound, in that it loses potency within from three to four weeks after the solutions have been mixed

2 The use of two different types of insulin daily, with its attendant responsibility on the patient.

3 Difficulties encountered by the less dexterous patient in handling the substance properly

Several months ago an improved insulin compound, technically called crystalline insulin, was submitted to us for clinical investigation by Dr. Melville Sahyun of Detroit. This insulin is a crystalline extract prepared from the pancreas. It is claimed that its action is more prolonged than standard insulin. It has the advantage of being as stable as standard insulin and is dispensed in a single solution.

A preliminary clinical report of the actions of standard, protamine and crystalline insulin on blood sugar levels is presented.⁶ Two normal subjects and fifteen diabetic patients studied over a period of four months form the basis of this report.

These patients were in the hospital on controlled weighed diets during each period of study. The available dextrose of the diets is divided equally between the three meals, as contrasted to the methods previously described.⁷ The meals were served at 8 a. m., noon, and 5 p. m. All patients were observed on each of the three types of insulin for a period of from ten to fourteen days before the blood sugar determinations presented in the accompanying charts were used as the basis for comparison.

In calculating the amount of insulin necessary for the patients in this study it was deemed advisable to keep the total number of units essentially the same as previously required in standard insulin. Thus, in

Chart 1—Comparative action of the different types of insulin on the blood sugar curve in a normal healthy fasting individual

patients who were receiving three doses of standard insulin daily the total number of units was redistributed into two doses daily, with the total amount increased or decreased according to the previous

twenty-four hour blood sugar curve. An attempt was made to keep the total number of units nearly constant rather than attempt to determine the minimal amounts of protamine and crystalline insulin required. However, in several patients it was necessary to reduce the amount of insulin administered because of the severe hypoglycemic reactions.

To determine the comparative action of the different types of insulin in the normal healthy person, a well

Chart 2—Comparative action of the different types of insulin on the blood sugar curve in a normal healthy individual on a controlled weight diet

balanced diet was given previous to the experiment. The individual was fasted for twenty-four hours and blood sugar determinations were taken every two hours over the last twelve hours of the fasting period. This was done to rule out the influence of the previously ingested food on the blood sugar curve. After the normal curve had been established for the subject, the effect of each type of insulin was determined every third day to rule out any possibility of the cumulative effect of previously administered insulin. After twelve hours of fasting, 10 units of each type of insulin was injected subcutaneously.

It will be noted in chart 1 that protamine insulin and crystalline insulin had somewhat similar effects on the blood sugar curve of a normal, healthy subject. The onset of the action of crystalline insulin is more rapid than that of protamine insulin, but its duration is not quite as long. In spite of the lack of a marked hypoglycemic level the subject complained of nervousness, inability to concentrate while reading and insomnia, which might be interpreted as symptoms indicative of a mild insulin reaction. This occurred with both protamine insulin and crystalline insulin and lasted for approximately one and a half hours. The hypoglycemic level produced by standard insulin was more marked but shorter in its duration.

The next study was the determination of the action of the "insulins" on a healthy subject who was on a normal controlled weighed diet. Blood sugar determinations were made every four hours throughout the twenty-four hour period. After the normal blood sugar level had been determined without insulin the patient was given 15 units of one kind of insulin at 7 a. m. and 7 p. m. on the days of the blood sugar determinations, and this routine was followed with each type of insulin. These studies were made at intervals of three days because of the reasons cited in the previous experiment. In chart 2 it is seen that standard insulin had a tendency to flatten the entire twenty-four hour curve whereas protamine insulin and crystalline insulin had only slight effects on the curve. It is interesting to note that following the administration of either protamine or crystalline insulin the subject's

6. Protamine Insulin supplied by Eli Lilly Company, Indianapolis. Crystalline Insulin Compound supplied by Frederick Stearns & Co., Detroit.
7. Hagedorn, Jensen, Krarup and Wedrup. *Acta Med. Scand.* 1932.

mild symptoms of hyperinsulinism between 1 and 2 a m. However, the blood sugar determinations made at that time were normal, even though nervousness, insomnia and perspiration of the hands were present.

These curves confirm the observations of previous investigators on the effect of standard insulin and protamine insulin. Crystalline insulin affects the curve more slowly than standard insulin but more rapidly than protamine insulin, and the duration of its action on the blood sugar level is not as long.

CLINICAL STUDIES OF DIABETIC PATIENTS

The diabetic patients in the report were for the most part taken from the diabetic clinic of the outpatient department of Harper Hospital. They were selected for study because of (1) the completeness of the previous records, in that all these patients had been observed in the clinic since the onset of their disease, (2) the difficulty of their being controlled on three daily doses of standard insulin, and (3) the marked fluctuation of blood sugar levels and the reactions accompanying these changes. The ages of these patients varied between 4 and 53 years. The duration of their disease (onset of symptoms) varied between one and twelve years, with a

Chart 3—Action on patient with severe diabetes exhibiting marked hypoglycemia and hyperglycemia with standard insulin.

general average of four and one-half years. All patients presented in this study were diabetic without other disease complications. Physical and laboratory examinations failed to reveal any condition, such as foci of infection, that would in any way alter the blood sugar curves.

The diets used were of two main types, i. e., the high carbohydrate low calory diet and the moderate carbohydrate maintenance diet.

In calculating the insulin dosage of the diabetic patient, no attempt was made to reduce the total number of units of insulin administered unless reactions occurred. Thus a standard of comparison was maintained throughout the study. The time of injection of protamine and crystalline insulin was kept constant in that it was administered at intervals of twelve hours.

Chart 3 shows the effects of protamine and crystalline insulin in reducing the marked fluctuations in the blood sugar levels throughout the twenty-four hour period. The "peaks and valleys" associated with the use of standard insulin were eliminated. The glycosuria was greatly reduced.

The case described in chart 4 exhibited the single "dip" type of blood sugar curve with standard insulin. The blood sugars were usually normal or somewhat

lower, at times associated with reactions, between midnight and 2 a m. The patient's fasting blood sugar level on the following morning invariably returned to the hyperglycemic level. Several attempts to eliminate the fluctuations of the blood sugar level were made by first giving the third dose of standard insulin later in the evening. This resulted only in a change in the time at which the hyperglycemia occurred. The addi-

Chart 4—Action on patient with severe diabetes exhibiting single dip hypoglycemia curve with standard insulin controlled by protamine insulin and crystalline insulin.

tion of a fourth dose of standard insulin reduced the fluctuations in the curve. However, the latter regimen was difficult for the patient to carry out because of his plan of living. When protamine or crystalline insulin was substituted, the flattening of the entire blood sugar curve resulted. Although there was a marked lowering of the blood sugar during the early hours of the morning, below the levels obtained with use of standard insulin, no severe reactions occurred and the fasting blood sugar did not return to its previous hyperglycemic level.

The effects of the various types of insulin are shown in chart 5. Here, as in several other patients observed, it was noted that crystalline insulin was more rapid in the onset of its action than protamine insulin. The duration of its effect on the blood sugar curve seems to be from two to four hours shorter.

Chart 5—Action on patient with moderately severe diabetes. Rate of onset of crystalline insulin is more rapid than protamine insulin.

The case described in chart 6 was extremely difficult to control with three or four doses of standard insulin. On the same diet and insulin regimen the patient would have a marked hypoglycemic reaction one day, but on the following day at the same hour hyperglycemia would be noted. This patient was extremely

sensitive to standard insulin and 2 or 3 additional units would precipitate a hypoglycemic reaction. Because of the lack of cooperation and illiteracy of the family it was impossible to establish an insulin regimen outside the hospital. However, with the use of two doses of either protamine insulin or crystalline insulin daily, the fluctuations in the blood sugar level disappeared. The

Chart 6—Action on patient with diabetes complicated by gangrene of foot.

severe hypoglycemic reactions were eliminated and the patient stated that she felt better.

The next step in this study was to determine the comparative action of standard, protamine and crystalline insulin when only one type of insulin was given twice daily, as contrasted with the administration of standard insulin as the morning dose and protamine or crystalline insulin as the evening dose (chart 7). As has been previously cited, it was possible to lower the blood sugar curve during the period of food with protamine and crystalline insulin. However, the use of standard insulin in the morning and either protamine or crystalline insulin in the evening produced the best results, as evidenced by the flattening of the entire twenty-four hour blood sugar curve. Lawrence³ has recently stated that protamine insulin does not adequately cope with the carbohydrate ingested during the entire day and does not prevent the increase in the blood sugar levels after meals, especially in cases of severe diabetes. It reacts remarkably well on the blood sugar curve during the latter period of the twenty-four hours. He found very little difference in the ability of protamine insulin to deal with the ingested carbohydrate regardless of the time the insulin was injected. This may be attributed to the slowness of its action or the time of administration. It was noted that a fasting hyperglycemia prevents the best results with the use of protamine or crystalline insulin as the morning dose, whereas, if the blood sugar level was within normal limits the rest of the twenty-four hour curve was lower. In general, crystalline insulin is more efficacious than protamine insulin in dealing with the blood sugar level during the period of ingestion of food.

BLOOD SUGAR LEVEL AND INSULIN ACTION

It would seem that the disturbance in the mechanism of the regulation of the blood sugar level in the diabetic patient is dependent on the change in the carbohydrate metabolism primarily in the liver. The blood

sugar curve may be altered by the rate of intestinal absorption of dextrose and also by the rate at which the tissues utilize dextrose. The latter change is affected by the amount of insulin in the blood and tissues.

Macleod⁸ points out that normally glycogenolysis proceeds more slowly than glycogenesis, whereas in the diabetic patient these processes proceed at an equal rate and hence little glycogen is stored. In the uncontrolled diabetic patient there is a continuous formation of dextrose and a decreased ability to store glycogen in the liver. Insulin injected in the diabetic patient restores the disturbed carbohydrate metabolism to normal by increasing glycogen formation and regulating the production of dextrose in the liver. Insulin injected in the normal subject disturbs the carbohydrate balance by overstimulating some phase in the previously described processes, with a resultant retardation in glycogen formation and storage.

Recent investigations⁹ have proved that the liver is more than a storehouse for glycogen, its function is controlling the blood sugar level and its role in the production of dextrose need clarification. Hyperglycemia may be due to the rapid release of dextrose from the liver owing to a change in glycogen storage to dextrose formation or utilization in the liver, or to the rate at which sugar is removed from the blood by the tissues. This imbalance in the glycogen-dextrose metabolism may be restored to normal by the use of insulin. Conversely, hypoglycemia in the diabetic patient would be interpreted as an increased formation of glycogen, a decrease in the rate of production of dextrose in the liver or an increased rate of dextrose utilization by the tissues.

Normally the body responds to hyperinsulinism in diabetic and normal subjects by release of glycogen which is aided by the increase of secretion of the adrenal glands. In uncontrolled diabetes the glycogen

Chart 7—Effect of standard insulin, protamine insulin and crystalline insulin given individually, as compared with effect of standard insulin as morning injection with protamine insulin and crystalline insulin as the evening dose.

stores of the liver and muscle are markedly depleted, the body being unable to deal with any emergency requirement for dextrose. The controlled diabetic and the normal subject who have greater stores of glycogen are better

able to cope with this demand. Can this in part be the explanation for the difference in the type and severity of the hypoglycemic reactions observed?

It is agreed that dextrose is essential to the fundamental physiologic metabolism of body cells. When this energy in the form of dextrose is markedly diminished, as in the case of hyperinsulinism in diabetic and normal subjects, certain irritative symptoms occur which are usually associated with low blood sugar levels. However, there have been reports of diabetic patients who had the clinical symptoms of hypoglycemia without the usual accompaniment of a low blood sugar level. Are these clinical observations to be explained on the rate of fall in the blood sugar content, or on the depletion of dextrose from the central nervous system in such a way as to impair the metabolism of the nerve cells regardless of the level of the blood sugar? Since protamine and crystalline insulin are slower in their action, the body is able to adjust itself to this dextrose demand. This is probably done in the uncontrolled diabetic patient by the production of dextrose from the intermediary metabolism of protein and possibly fat. The body cells are supplied dextrose in amounts sufficient to carry out their fundamental basal metabolism and prevent irritative symptoms (hypoglycemia). Could the severe reactions seen after the injection of standard insulin, and the comparatively mild symptoms observed after the injection of protamine or crystalline insulin, even though the blood sugar was markedly lowered, be explained in this way?

COMMENT

All diabetic subjects vary in their response to standard insulin therapy. Some are "insulin sensitive," in that insulin produces a marked effect on the blood sugar level. Others are "insulin resistant," in that insulin has only a slight effect on the blood sugar level. The same phenomenon has been observed with the use of protamine and crystalline insulin and may be the explanation of the varying response of diabetic patients to the types of insulin studies in this report.

Though no attempt was made to determine the minimum dosage of protamine, in some instances the twenty-four hour blood sugar curve could be controlled by the use of protamine insulin twice daily. Crystalline insulin seemed more effective in this regard. However, the best results in the cases of very severe diabetes were obtained with the administration of standard insulin as the morning dose and protamine or crystalline insulin as the evening dose. It is important to reemphasize that when the use of two doses of standard insulin gives the best results the use of protamine or crystalline insulin is of no special value.

The treatment of diabetic coma with protamine or crystalline insulin has thus far been unsatisfactory; standard insulin is to be preferred because of its more rapid action. However, by supplementing standard insulin with protamine or crystalline insulin, a more constant and prolonged effect on the lowering of the blood sugar level and the disappearance of the ketosis was observed.

SUMMARY

This study confirms the observations of previous investigators with regard to the action of protamine insulin. The crystalline insulin compound used in this study has an action similar to protamine insulin. It diminishes the fluctuations in the blood sugar level and also decreases the severity and frequency of the hypoglycemic reactions commonly seen with the use of

standard insulin. Crystalline insulin is more rapid in the onset of action and shorter in the duration of its effect on the blood sugar level, in contrast with protamine insulin. Its action on the blood sugar level lasts for a period of from eight to nine hours and returns slowly to its normal level. The number of doses and amount of insulin required to control the blood sugar level is reduced as compared to the use of standard insulin. It is similar to standard insulin in that it is a stable compound and is dispensed in a single solution.

Clinical Notes, Suggestions and New Instruments

TULAREMIA AND PREGNANCY REPORT OF A CASE

DUDLEY P. BOWE, M.D. BALTIMORE, AND DON C.
WAKEMAN, M.D. TOPEKA, KAN.

There is an abundance of literature on tularemia, but there has been no careful study of the disease occurring as a complication of pregnancy. Kavanaugh¹ presents an excellent review of 123 cases, stating that "three patients contracted tularemia during pregnancy and were delivered of babies during the height of the infection. In one case labor was premature. The disease did not differ from its usual trend." The following case, occurring in midpregnancy, is presented because of the lack of available data on the disease as a complication of the gravid state, its effect on the maternal organism, and the effect on the fetus.

REPORT OF CASE

Mrs. I. A., a white woman, aged 40, seen in the accident room of the St. Agnes Hospital, Baltimore, Jan. 15, 1935, complained of ulcers on the fingers and a painful swelling on the left arm. She stated that while dressing a rabbit twelve days before (Dec. 24, 1934) she had scratched her left thumb with a splinter of bone. Three days later she noticed a little redness and swelling of the injured thumb. Then a small ulcer developed and in rapid succession there appeared ulcers on the fingers of both hands. At the same time she began having anorexia, fever, frequent chills and sweats and general malaise. December 29 she noticed a painful swelling on the medial surface of the left arm at about the middle third of the humerus.

There was no family history of tuberculosis, diabetes, malignancy or hemorrhagic diseases. The patient's health had always been good except for childhood measles and whooping cough, and there had been nine pregnancies without complications, terminating in full term normal deliveries, all children living and well at the present time. The menses started at the age of 12 and had always been regular and normal except for interruptions during pregnancies. The last menstrual period was in August 1934 and she first felt life early in December. The review of systems revealed nothing except bad teeth, with frequent attacks of toothache.

On physical examination the patient was well nourished, with noticeable pallor of the face and mucous membranes, and a temperature of 100 F. The pupils were regular and equal and reacted to light and in accommodation; the conjunctivae were clear, and the external ocular muscles were normal. The nasal septum was intact and the nares were patent. The hearing was good. The tongue and buccal mucosa were pale; many teeth were discolored and contained cavities, and the gums were retracted. The pharynx was normal. There was no cervical glandular enlargement and the thyroid was not palpable. The chest was symmetrical; expansion was free and equal, resonance, fremitus and breath sounds were normal, and there were no adventitious sounds. The heart was not enlarged or displaced and there were no murmurs. The rhythm was regular, the blood pressure was 135 systolic, 80 diastolic, peripheral vessels

¹ Kavanaugh, C. M. Tularemia. A Consideration of 123 Cases with Autopsy in One Arch. Int. Med. 65: 61 (Jan.) 1935.

were soft and the rate was 100 per minute. There was an abdominal mass, apparently the uterus, which was symmetrical, smooth and reaching to the umbilicus, fetal parts could be palpated, and the fetal heart was audible in the left lower quadrant. The liver, kidneys and spleen were not palpable. There were no abnormalities of the spine. Vaginal examination revealed a relaxed perineum with moderate rectocele and cystocele, the cervix was soft in consistency and the uterus enlarged, the adnexa were not palpable. On the palmar surfaces of both thumbs and on the second, third and fourth fingers of the left hand there were pustular ulcers varying in size from 4 mm to 1 cm in diameter, with grayish white bases surrounded by elevated reddened areas. On the medial surface of the left arm, at the middle of the humerus, was a firm red, indurated, tender, elevated area 3 cm wide with a crusted surface, apparently a subcutaneous nodule. The glands of both axillae were enlarged and tender. When she was admitted to the hospital she gave the impression of tularemia of the ulceroglandular type and pregnancy.

Examination of the blood showed erythrocytes 3,500,000, white blood cells 5,250 per cubic millimeter hemoglobin 70 per cent, color index 0.83, polymorphonuclears 66 per cent, lymphocytes 24 per cent, and large monocytes 10 per cent. The blood Wassermann reaction was negative, the urine contained one plus albumin and a few pus cells, and agglutination tests² proved the diagnosis of tularemia, with agglutination in a dilution of 1:640.

She remained in the hospital for fourteen days and after the day of admission her temperature was at no time above normal. Because of this, the Foshay serum was not used and treatment consisted of local application of moist heat to the ulcers, with ice bags to the enlarged glands and general nursing care. The fetal heart was observed carefully and remained unaffected. She was sent home after the disappearance of the ulcers, the subcutaneous nodule, and the enlarged axillary glands and returned to the antepartum clinic at intervals for antepartum routine and repeated agglutination tests. The antepartum course was uneventful until April 4, 1935, at which time she complained of painless bleeding for eight hours, passing clots and using a total of fourteen pads. On rectal examination the cervix was felt to be dilated 3 cm and was very soft, but no placental

tissue could be palpated. The head was floating. A sterile pelvic examination definitely excluded the possibility of placenta praevia. The bleeding continued for another eight hours without pains. The blood contained 3,180,000 red blood cells, 7,400 white blood cells, 58 per cent hemoglobin, 82 per cent polymorphonuclears, 13 per cent lymphocytes, 5 per cent large monocytes, and 133,500 platelets per cubic millimeter. There was slight anisocytosis, the coagulation time was three minutes (Lee and White) and the bleeding time was one and one-half minutes. Urinalysis was essentially negative. Because of the continued bleeding and anemia it was decided that it would be advisable to induce labor which was done by artificial rupture of the membranes slowly draining about 1,000 cc of amniotic fluid. Two hours later after deep engagement of the head and a few slight pains 2 minims (0.12 cc.) of solution of posterior pituitary was administered hypodermically and the child delivered spontaneously after about a dozen pains. The placenta was easily expressed and there was loss of only about 150 cc. postpartum blood.

The male infant breathed spontaneously, weighed 6 pounds 12 ounces (3,090 Gm.) and was apparently mature. The head

diameters were bitemporal 8 cm., biparietal 9 cm., suboccipitobregmatic circumference 33 cm., the occipitofrontal 31.5 cm. and the shoulders 33.4 cm. A thorough examination of the child revealed no abnormalities. The blood counts at birth were 6,000,000 red blood cells, 5,500 white blood cells, 115 per cent hemoglobin, 80 per cent polymorphonuclears, 10 per cent lymphocytes, 2 per cent transitional cells, and 8 per cent monocytes. In six days there were 4,630,000 red blood cells, 10,500 white blood cells, 100 per cent hemoglobin, 70 per cent polymorphonuclears, 28 per cent lymphocytes and 2 per cent transitional cells. Blood drawn from the infant two hours after birth contained agglutinins for *Bacterium tularensis* in low dilutions. The child was circumcised on the eighth day of life and weighed

7 pounds 7 ounces (3,374 Gm.) on the tenth day, 11 ounces (313 Gm.) above birth weight after a neonatal loss of 4 ounces (114 Gm.). It was breast fed.

The pathologist's report, by Dr. H. S. Everett, was as follows: The placenta was about 18 by 15 by 4 cm. The cord was centrally inserted. On the maternal surface were numerous opaque white spots from 5 mm to 1 cm. in diameter which on section showed white hyalinized nodules, some of which showed hemorrhagic centers.

Microscopic sections showed white infarcts with necrosis and replacement of tissues by fibrin. Villi were well formed and the decidua was partly hyalinized, but there was no evidence of inflammatory reaction. The diagnosis was multiple white infarcts of placenta.

The mother had an uneventful postpartum course and blood counts on alternate days showed a slight increase in erythrocytes and hemoglobin with liver and iron therapy.

COMMENT

The apparent effects on the course of the pregnancy and parturition were the moderate anemia of the hypochromic type and uterine bleeding before the onset of labor. The bleeding probably can be attributed to extensive placental infarction, since there was no evidence of a disturbance of blood coagulation. The infant showed no evidence of disease except for the presence of agglutinins in low dilutions (1:80) but this is more than one would expect to be due to the so called normal agglutinins which may cause agglutination in dilutions of 1 to 5.³ This may represent antibody formation by the fetus as the result of bacterial invasion through the placental villi or placental transmission of maternally produced agglutinins. Many of the acute infectious diseases have been demonstrated in the fetus. The increase in the titer of the child's blood indicates that the mother's milk may have also transmitted antibodies as the child started breast feeding twelve hours after birth. De Lee⁴ suggests that this may occur with diphtheria and tetanus toxins and typhoid. In this case the disease was mild in the acute stage was of short duration, and the pregnancy was apparently not endangered by the infection.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, MD
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed the series will be published in book form.—ED

THE THERAPY OF PSYCHONEUROSES

IN COLLABORATION WITH S. H. KRAINES, MD

"Functional disorders" are just as real disorders as are "organic disorders." Patients with neurotic manifestations are not simply "imagining." The pain that the querulous woman complains of is just as real to her as if it were of organic etiology. The paralysis of the hysterical patient defies voluntary movement as greatly as does that of the hemiplegic individual. These symptoms are not only real to the patient, they hurt and incapacitate him even more than when there is an organic basis, because of the associated mental attitude.

Functional and organic disorders are neither independent, antagonistic nor mutually exclusive of each other. They interact in the most complex patterns. Organic disease is often accompanied by psychoneurotic disturbance, the two may coexist independently of each other, and the latter may eventuate in organic disease. As examples of this correlation may be cited certain forms of hyperthyroidism, so-called pseudo-angina pectoris, "essential" hypertension, and the "gastro-intestinal neuroses" which by indefinable stages merge into peptic ulcer, or colon spasm and mucous colitis. A person with a tendency to diabetes may not develop the clinical disease until after he has gone through an emotional crisis. Many of these conditions can be temporarily relieved by other means, but their obstinate tendency to recurrence can be cured only by discovering and remedying the psychoneurotic disturbance underlying them.

Therefore, successful treatment of all excepting purely physical diseases demands that every patient, whether evidently psychoneurotic or not, be given, in addition to a thorough physical and clinical examination, a social analysis and a personality study—a total analysis.

THE DIAGNOSTIC ANALYSIS

A thorough understanding of the patient's physical condition is, of course, of paramount importance, and it goes without saying that every psychoneurotic individual should have an exceedingly careful physical examination at the beginning of the treatment rather than continuously or frequently repeated. The suggestive influence of a thorough diagnostic "work-up" is inestimable. For, if one can assure the patient after such an ordeal that nothing abnormal has been found, it will go a long way toward relieving his fears with their evil consequences. The objection to frequently repeated reexaminations is that these may carry with them the unfavorable suggestions that the physician is not sure of his ground.

It will help in the understanding of the dynamics of the psychoneuroses to fix our attention on emotion as

the motor mechanism—emotion, be it understood, differing from intellectual processes precisely by the degree to which the "intero-effective" division (the autonomic nervous system and the endocrines) enter into the process.

That, in point of fact, many of the symptoms found in psychoneurotic individuals are due to exaggerated activity of the autonomic nervous system and of the endocrines may be illustrated by the dilated pupil, the tendency to sweating (especially of the hands) and the tachycardia occurring in cases that cannot be classified as exophthalmic goiter or by the cases of blood pressure elevation occurring independently of arteriosclerosis and responding so readily to the proper treatment that they cannot well be considered instances of the condition known as essential arterial hypertension. Finally, what better example of this relation could be found than the amenorrhea that occurs in pseudocyesis as well as in women who greatly fear pregnancy?

A large number of the phenomena of psychoneuroses are due to vicious circles set up by these autonomic and endocrine disturbances. The emotionally induced disturbance of secretions and motility of the gastrointestinal tract reflects itself in the symptoms of anorexia, indigestion, constipation and colon spasm. This disturbance of the digestive system is followed by malnutrition, which in turn increases the weakness and irritability of the nervous system. To the anorexia and constipation we might add insomnia, the third most common presenting symptom of psychoneuroses—a trio which forms a syndrome so characteristic of this kind of disturbance that it may be called the "psychoneurotic triad." The insomnia, due to such emotional disturbances as worry and fear, results in excessive fatigability the next day, which in turn increases the insomnia, for, once fatigue exceeds the physiologic limit, it hinders rather than favors sleep. No less important is the fact that fatigue and weakness breed pessimism, which in turn results in unconquerable worry and fear.

From what has just been said it is obvious that the degree to which emotion enters in the clinical picture must be determined, for, until organic disease results, emotional reactions persist only so long as the emotion persists. Emotion should be visualized as the zone of contact between the "intellect" and the somatic processes with the diencephalon as the "switchboard," the autonomic nervous system as the connecting link, the viscera as the keyboard and the endocrine glands as substations that reinforce and continue the somatic commotion once it is started. Such commotion in turn aggravates the emotional storm so that, unless something is done to allay it, the condition goes from bad to worse. Therapeutically one may break in on the vicious circle at any one of several points, but, unless one succeeds in removing the causative emotion, the results are generally but temporary.

Striking at the root of these disturbances is greatly helped by the understanding that pathogenic emotional reactions are largely due to unresolved conflicts. To discover these unresolved conflicts the patient must be subjected to a personality study.

In the interpretation of the symptoms of psychoneuroses and of suppressed unresolved complexes, the concept of symbolism is of great importance. A symbol is something that stands for a certain idea or group of ideas. Thus the flag is a symbol. The soldier or the patriot does not fight for the bit of bunting carried on the end of a stick. It is the loyalty, the devotion to home, the opinion of his fellow men and many other

factors that are behind the devotion to the symbol, the "flag." It should be stressed that symbols have meanings only to the individual person or group, the German flag may arouse no emotion in the French, nor the Japanese flag in the Chinese, except possibly that of antagonism.

The word "symbol" is employed in psychiatry in the same sense. The patient who has a hysterically paralyzed arm is merely using the paralysis of the arm as a symbol for certain ideas. The pains that so many middle-aged neurotic women feel in the abdomen, the heart or the head are in large part symbolic, expressing certain repressed ideas. To the affected individual the "neurotic" pain is real, and the fact that the pain is a symbol carries all the more weight because there is an emotional upset associated with it. If one always keeps in mind that in psychoneurotic persons many symptoms are symbols, an important advance in the understanding of the patient will be made.

In order to find out wherein these repressions lie, one of the most important things is to establish a rapport between the patient and the physician. The patient must have sufficient confidence in the physician to reveal the innermost secrets of his heart, to reveal those very things that he has never told any one else. In psychiatric hospitals, one often comes across patients who, even though devout Catholics, have never told their secret to the priest but who, in the proper setting, unburden themselves to the physician. The exact technique varies greatly with the individual but, generally speaking, if the patient is allowed to talk with but few interruptions, he will bring forth many of his so-called subconscious ideas. A gentle hunt dropped here and there which shows that the physician does not become shocked because a person does not subscribe to all the conventional tabus of the day goes a long way toward releasing the inhibitions of the individual to the telling of his story. Sometimes a pointed question brings tears to the patient's eyes, an indication that a sore point has been touched. It is then the physician's duty to proceed with his probing as he would in case of a sinus to discover what is at the bottom of it that keeps it from healing. As the physician palpates an abscess, even though it is painful, to determine the best place for an incision to let out the pus, so must he persevere in following up the painful thoughts to discover the best means of relieving the patient of their baneful effects. If these means are not sufficient, one must resort to the analysis of dreams, to the "free association" method and occasionally to hypnosis. Many patients can be relieved of their long enduring fears by several interviews, but in some cases many months may have to be spent in digging out the repressed ideas.

One illustration may suffice.

A girl complained of terrifying obsessions. For months she dreamed of killing little children. Her fears prevented her from sleeping in a home where a small nephew was present. The obsession grew on her to the point that she thought of suicide. In this case it was found that a few weeks before the onset of her obsessions she had submitted to an abortion. As she was unmarried there were many complications. She grieved over the crime of killing an unborn child. She read the newspaper story of a couple killing a child and then the obsessions came on. The obsessive ideas of killing children was her method of symbolizing the killing of her own unborn child. She repressed the memory of the incident, but it lived on in this symbolic form. In two interviews the patient understood the connection and her obsessions disappeared. Since she understood what idea she was trying to express (the reproach

over the abortion) she had no need to symbolize it, therefore the disappearance of the obsession. The reproach itself was simply handled.

It is in this field that the psychoanalysts have done their greatest good. They have encouraged the patient to talk and in this manner have brought out the repressions. Unfortunately, psychoanalysts have permitted themselves to raise fanciful superstructures of theory on the basis of these simple facts and to draw wild conclusions from them. In spite of these excrescences of the system, the psychoanalysts at times do get beneficial results. This is due, it seems, mainly to the fact that the patients talk themselves out and learn to appreciate the psychic phenomena at their true worth. The patients also get much benefit from the reassurance that springs from the indomitable and irrepressible faith that the psychoanalyst has in his own treatment. Even if the patients go away with their heads filled with all sorts of unproved speculation and theory, it matters little as long as they have improved.

With these concepts in mind, the treatment of the psychoneurotic patient may possibly be begun, with the feeling that one practices rationally. If one discovers what the repressed ideas are for which the symbols are used and teaches the patient to face the facts, the symbol will no longer be necessary, for, when the individual can be made to understand what the thoughts are that cause him to have symbols, the thoughts can be consciously expressed and consequently there will be no need for their symbolic expression. While matters are not always as simple as this, one not infrequently at least, secures a therapeutic triumph from the application of these principles.

THE THERAPEUTIC SYNTHESIS

The treatment of psychoneuroses may be resolved into the following indications:

- 1 Proper care of physical defects
- 2 Changing the patient's personality
- 3 Lessening environmental strain as much as possible.

1 Remedying physical defects should, of course be attended to primarily, but only so far as necessary to make the patient more adequate to meet the strains of his life.

(a) Surgery. One must be particularly conservative in advising surgery in the psychoneurotic. An operation should be advised only if one feels sure, first that the patient's physical condition will be so greatly improved by the operation as to give him a new start in life and, secondly, that he will submit to the operation. One occasionally sees patients unimproved by operations because these did not strike the root of the disturbance. Individuals who have had thyroidectomies simply because they were nervous and had a slightly elevated metabolic rate, parous women who have had repairs of lacerated perineum and cervix, and persons who have had nephropexy or appendectomy, that did not relieve them for more than a short time if at all. Such patients may thereafter make it their life's business to discredit surgery and keep others, who need an operation from securing its benefits. It is also a fact that merely advising operation constitutes a potential psychic trauma. The patient who has been advised to have an operation and rejects it has been harmed by the advice. He is liable to brood over the terrible doubt within him and the dreaded operation he does not have the courage to undergo. He may lose sleep and the joy of living. Such a patient may shut himself out after, all "regular physicians" in fear that the

give him the same advice. If he then fortunately happens to be cured by some quackery or other, such a person becomes an ardent propagandist for this form of treatment, which in turn may wreck the chances for cure of many another sick fellow man.

One may be more generous about advising diet or medication than surgery, but these too must be prescribed with discrimination.

(b) Diet. Many of these patients are diet cranks and faddists. They crave having special diets prescribed for them, and yet such dieting may be harmful to them by acting as a constant suggestion that they are sick. The dietary of the psychoneurotic should, as far as possible, include everything that goes to make up a normal general diet and the importance of "eating everything" be impressed on the patient. The very multiplicity and bizarre of the dietary tabus of these individuals are often directly diagnostic of the psychoneurotic foundation for them. By continually refusing certain articles of food, the patient may have gotten himself into a condition of malnutrition or hypovitaminosis. Indeed, the patient may have to favor the very food that he has been in the habit of avoiding. Thus, some of these individuals have been starving themselves of carbohydrate to acquire the stylish sylph-like shape and they may require an abundance of bread and butter prescribed for them to acquire the euphoric embonpoint. Anemia is common in those who refuse to eat eggs, and these most iron-rich of foods may be the important reconstructive tonic. Allergy must, of course, have been excluded when giving orders for diet.

(c) Medicinal treatment directed toward improving the patient's physical condition properly furnishes the medicine so much desired by most of these patients, but one should ever beware of routine placeboing. The very fact that a medicine is prescribed serves as a potent suggestion that something physical is wrong. It may "fix" the disease on the patient instead of curing it. Indeed, the psychoneurotic patient is not really cured until he is free from medicine taking.

For the temporary relief of insomnia a sedative may be desirable. For instance, bromide (prescription 1) to lessen excessive nervous irritability. If bromide is not sufficiently powerful, carbromal (prescription 2) may be of value. In patients who have acne, some other sedative may be desirable, e. g., barbitol (prescription 3) or phenobarbital (prescription 4). It is best, in general, to give these in subhypnotic divided doses—after meals and at bedtime—rather than to force sleep by means of a large dose of the more powerful hypnotic taken at bedtime only, as there is great danger of narcotic habit formation in these individuals. It is also of great importance for the patient to realize that the sedative is merely an adjunct, to break in on a vicious circle, that it is merely a crutch that must soon be abandoned as otherwise it weakens instead of strengthens. The same principles govern the use of cathartics. (See therapy of Colon Stasis.)

(d) Hydrotherapy in the form of prolonged warm baths, which can be taken in any average home, has a very soothing effect. Soaking in warm water (about 92 to 98 F) for at least an hour will often bring blissful relaxation. Cold showers in the morning are to be recommended at times as a physical stimulant and a training in subjecting oneself to unpleasant experiences for the benefit to be derived in consequence. They also increase resistance to the unfavorable effects of chilling.

2 Changing the patient's personality must be the focal point of therapy of the psychoneuroses. This

indication is so difficult to carry out as to make its accomplishment almost a miracle, but the results are no less miraculous.

This change may be accomplished at times by acquainting the patient with his/our basic multiple personality. To simplify the presentation to the patient, it may be presented in somewhat the following manner: "We all have living within us, as our direct and most intimate heritage from our ancestors, a savage, a veritable beast, call it the "id" with Freud or the "anima" with Jung. This is overlaid by a more or less efficient veneer of culture, the result of civilization which makes us socially acceptable and which Jung calls the "persona," the self we want to be and do our best to imagine ourselves to be. The well balanced, happy individual is he whose "anima" and "persona" are in friendly relation with each other, whose persona frankly recog-

PRESCRIPTION 1—Bromide

| | | |
|---|----------------------|--|
| R | Potassium bromide | 30.00 Gm |
| | Anise water | 30.00 cc. |
| | Syrup of glycyrrhiza | to make 120.00 cc. |
| M | Label | Teaspoonful in milk after meals and at bedtime |

PRESCRIPTION 2—Carbromal

| | | |
|-------|---------------------------------|----------|
| R | 25 carbromal tablets | 0.30 Gm. |
| Label | One after meals and at bedtime. | |

PRESCRIPTION 3—Barbitol

| | | |
|-------|------------------------------------|---------|
| R | Barbitol | 3.00 Gm |
| | Divide into 30 capsules | |
| Label | One after meals and two at bedtime | |

PRESCRIPTION 4—Phenobarbital

| | | |
|---|---------------|--|
| R | Phenobarbital | 0.80 Gm |
| | Iso-elixir | 100.00 cc. |
| M | Label | Teaspoonful in a little water after meals and at bedtime |

NOTE.—This is an example of prescribing of a "magistral formula in contradistinction to ordering of an official or a proprietary formula. The advantage of taking the slight trouble to prescribe medicines as a magistral formula rather than otherwise lies in the possibility of readily adjusting the size of the dose to the effect desired. If one prescribes the N F Elixir of Phenobarbital or what is more expensive, a proprietary elixir of this kind, one gets only 0.02 Gm. per 5 cc. teaspoonful. The foregoing prescription carries twice as much. If the patient gets too drowsy from such medication the dose can readily be reduced or it can be increased if he does not get sufficient sedative effect without having to order two or more teaspoonfuls which greatly increases the expense of the medicine to the patient. The "iso-elixir" employed in this prescription is now official in the National Formulary. It is a device by which the physician may secure the cooperation of the pharmacist in the adjustment of the proper alcoholic strength of the vehicle. The N F VI recognizes two basic elixirs, a Low Alcoholic Elixir and a High Alcoholic Elixir. These two are miscible with each other in all proportions and the following note is appended to the monograph.

Iso-Alcoholic Elixir (Iso-elixir) is intended to serve as a general vehicle for various medicaments that require solvents of different alcoholic strengths. When therefore, Iso-Alcoholic Elixir is specified in a prescription that proportion of its two ingredients is to be used that will produce a perfect solution.

As phenobarbital is alcohol soluble and water insoluble the pharmacist will employ the High Alcoholic Elixir in preparing this solution.

nizes the insistent demands of self preservation (fear, hunger, acquisitiveness, ambition) and of race preservation (sex, parental love, altruism, patriotism) which strives conscientiously to gratify these in a socially acceptable manner. The individual whose two selves are not on speaking terms with each other is essentially unhappy and dissatisfied. These are the ones whose repressions may result in pathogenic symbolism. By making the patient self tolerant and self understanding, one may be able to effect the necessary personality change.

The frank acceptance of ourselves as we are is therefore an important goal in the treatment. It is an important remedy for an inferiority complex. Thus an individual who has a deformed limb, strabismus, blindness or deafness is liable to develop such a feeling of inferiority because of his handicap. Such a person must be trained to accept his defect as a matter of course and to compensate for his deficiency by excelling in some other direction. These deficiencies constitute no real handicap to the person who is determined to

get on. The inferiority complex resulting from social or sex maladjustment or financial difficulties may be frankly accepted and compensated for in the same way.

Substitution therapy is based on the fact that the desires within us have a drive or energy behind them that continues in spite of the fact that the desires cannot be fulfilled and are liable to result in untoward manifestations unless they are diverted into other channels. Substitution may be employed also in the breaking of bad habits. The inveterate smoker continues to wish to smoke after his pledge to give it up. There is still the energy present urging the person to fulfil his wish. Therefore, to break the habit, one must deal with this drive or energy. One of the best ways is to substitute some other means of utilizing this energy so that it will be less troublesome. Thus, the chewing of gum to the smoker, the providing of active and dressy boy scout group activities to the adolescent gangster, the use of play groups and toys in the case of the infant indulging in masturbation, all represent the substitution of some method of releasing and utilizing the energy otherwise directed into undesirable channels.

To all of us, the presence of some goal in life acts to give zest to living. There are two types of goals, one that is unattainable and ever receding, as exemplified by the admonition to "hitch your wagon to a star." The other type is a series of goals, each of which can be attained relatively easily and in a reasonably short time steps, as it were, in the attainment of a greater goal. Surmounting each such step gives satisfaction and it is the satisfaction of attainment that is the important thing.

Sex hygiene is vital. The presence of erotic disturbances in so many patients warrants the formulation of the sexual problem to each individual. Patients are often helped by removal of the feeling of guilt over their natural sex urge or over undesirable results to which it has driven them. Once a mistake has been made, it may be condoned if the socially more acceptable and hygienically safer form of life is adopted for the future. Much of the difficulty and infelicity of married life is due to remediable sexual maladjustment and much good can often be accomplished by a frank discussion of the difficulties.

Proper habit formation is one of the great functions of hygiene habits not only in the daily way of doing things but in emotional response as well. Children may develop habits of emotion instability that are often carried through life. Whereas it is true that the fundamental constitution of the individual so often determines what type of affect is present, nevertheless it is also true that these fundamental emotional drives can be greatly ameliorated and changed. Persons who are subject to violent outbursts of temper may be helped by pointing out to them methods of control. Thus, the patient may be urged the next time he becomes excited to turn around and walk into another room until his anger blows over. The fact is stressed that he is too excitable and that he can in time by continued practice, learn to "thicken his skin" so that he is not so easily aroused. When this is combined with readjustment of the personality in other ways, surprising results can often be obtained.

Socialization is of extreme importance to many patients, who sitting alone in their homes, brooding over their aches and pains and fears miss the wholesome companionship of the "other fellow." Many examples can be cited of "neurotic women" whose aches

and pains were greatly helped by becoming active members of benevolent or reform organizations. They did not have time to think of their own ailments, in the interest of what others were doing.

Occupation Therapy. A program of daily activities should be outlined for the patient with his cooperation and in consultation with his desires. The day should be so arranged that there is something being done all the time, the purpose being to allow little opportunity for brooding, and to instil new and stimulating ideas for some, walking, for others listening to the radio or seeing the movies, or doing some special work. The type of program depends entirely on the individual. It is at this point that hobbies have a significant role. Often the daily work of the individual is a compulsory matter, his life's vocation being merely a necessary evil by means of which he can subsist. To such persons the development of avocations, of hobbies, brings great relief. The doing of something other than one's work, the getting of pleasure out of accomplishing things that do not have to be done, are of great value in relieving the tedium of life and making the patient happy. Right here it might be well to note that concrete realities are the best type of hobbies. By this it is meant that individuals who tend to be day dreamers should not develop the reading of books as their hobby. This is too abstract, they need much more concrete and real things. The development of a carpentry shop where they can make and feel and see their own creations, the collection of stamps, photography, the care of a garden or the raising of pets is better for this purpose. "Fancy work" has a curative tendency for many a neurotic woman.

Diversion and fun are the only way in which we can secure a vacation from our accustomed thoughts during waking hours. The more the thoughts are inclined to be morbid, the more are we in need of such diversion. Movies, the theater, concerts, parties and picnics, travel, all have a therapeutic value, most especially for those who have been largely denied them. Of the requirements for a proper mode of living—a sufficient amount of work, a sufficient amount of rest, a sufficient amount of food and a sufficient amount of fun—the last is not the least.

Often it is necessary to desensitize a person to some painful memory. The case of the girl who developed obsessive thoughts as a result of the "painful memory" of the abortion illustrates the need of making this "memory" less painful. This is carried out almost in the same fashion as desensitization for an allergen. The topic of such emotion is discussed a little at a time and at frequent intervals, until finally the patient is no longer so sensitive about it. It should be noted that it is not the obsession or the "peculiar idea" that is discussed but the etiologic factor, the "painful memory." When, on the other hand, a patient borders on the psychotic and presents fixed delusions, he should never be argued with as to his delusion. Controversy often tends to fix and harden ideas of fancy that disappear if not touched on.

Suggestion, or the implanting of a dominant idea in the mind of another individual without process of reasoning or persuasion, is ever present in all forms of therapeutic endeavor. The very fact that a patient submits to any kind of treatment with faith that it will help him carries with it a potent suggestion that it will do so. This is indirect suggestion, in contrast to direct suggestion which is exerted by the therapist.

expresses in words the idea one wishes to implant in the mind of the other individual. Thus, the statement "I will cure you" is a direct suggestion, the curative potency of which is in proportion to the faith the patient has in the one who makes the statement. Suggestion is the chief stock in trade of the quack, who promises a cure regardless of his ability to perform it and by that act alone often cures those curable by suggestion. Scientific physicians, on the other hand, do not resort to this potent measure often because they are harassed by honest doubts as to the completeness of their understanding of the case. While we cannot afford to sacrifice honesty—the distinguishing feature between the quack and the physician—we should employ such direct suggestion as "You will get well" whenever we have no reasonable doubt of the truth of this statement. We often neglect to do so because it seems so obvious to us. It may not be to the patient.

Suggestion by itself is capable of removing all those symptoms due to suggestion, but it is merely of symptomatic value. It does not cure the psychoneurosis itself. Suggestion is therefore of much less importance than training the patient to understand himself and to deal effectively with his problems. It is, nevertheless, true that the credulous are influenced more readily by suggestion than by persuasion, also, that suggestion is of importance in every case. The very manner, words and look of the physician have a suggestive influence of profound importance. The physician who can make his patient feel that he is his friend and can carry the conviction that he will do his best to help has a healing potency within himself. The physician to whom the patient can tell his troubles with certainty of sympathy and understanding and the expectancy of relief can give much help. It should be the aim of every physician to treat his patient so that he feels better for having had the consultation. Some patients feel better even the moment they lay eyes on the physician.

In many cases in which the individual is of inferior intelligence or the time available is short, hypnosis is of value. It must, however, be realized that hypnosis (a form of suggestion) is similar to medication in that it is only a temporary measure, that lasting results are not likely to be obtained unless a personality readjustment is accomplished. One finds many hysterical persons cleared of their symptoms by hypnosis, only to return at some future time with a different type of symptom, brought on by the same factors that caused the first symptom.

3 Lessening environmental stress is often possible by adjustments in the patient's surroundings. Such adjustment will go a long way toward helping in stabilization of the patient. Often one can accomplish much by treatment of the relative (husband, wife or parent) who is the irritating factor. For instance, a husband too "busy" to give his wife the companionship she craves may be made to see the error of his ways. A patient who developed a marked change in personality following a head trauma, with symptoms of great sexual drive and of explosive irritability, was nicely handled by making the wife more understanding, sympathetic and accommodating.

Change of environment may generally be secured most easily by a "vacation," and the physician who does not have it among his *materia therapeutica* misses a powerful weapon in his armamentarium. By advising

a temporary change of environment one can often discover to what extent the accustomed environment is detrimental to the patient.

A changed environment may do more than anything else toward promptly relieving the symptoms of maladjustment. It is often surprising to see how a child that has been living in a "temperamental home" and is afflicted with temper tantrums with hypochondriacal aches or pains or with enuresis, will improve in a relatively short period in more stable surroundings. For many a "nervous" child, its mother—herself "nervous"—is its worst enemy. Adults, being merely "children grown up," react in the same way.

Whenever an individual improves on going away from "home" and relapses on returning to it, his habitual surroundings are thereby revealed as pathogenic and the exact nature of the pathogen may then become discoverable. The patient may have to be permanently removed from the unfavorable influence, unless it is possible, by methods previously described, to immunize him to its evil effects.

Securing an abundance of rest as well as a sufficient amount of work is a *sine qua non* with psychoneurotic patients. Excessive fatigue as well as excessive leisure are toxic factors that must be resolutely eliminated, for fatigue breeds pessimism and it may be pessimism that makes the conflict unresolvable, the situation unbearable. An after dinner nap is often a better sedative than any medicine that may be prescribed. A partial rest cure for a month or more should be insisted on for patients who are much underweight as well as for those who, on account of overwork with tension and insomnia, are in danger of the narcotic habit. Just as excessive fatigue begets restlessness and insomnia, so rest begets rest in these individuals. For example, a partial rest cure for an overworked housewife requires hiring of help so that the amount of work required of the individual may be sufficiently reduced to permit increasing the amount of time spent in rest and relaxation, e g, breakfast in bed and one or two hours' rest afterward, an after dinner nap of an hour or two, and going to bed right after supper. As the patient improves, the time in bed is progressively diminished.

Physicians must, however, beware of diagnosing overfatigue and prescribing a rest cure merely because the patient declares himself tired. The work may be so uncongenial as to "make the patient tired" without actually overfatiguing him. Or the individual may be of the self-indulgent type and suffer from a premature sense of fatigue. Such patients need to be strongly encouraged to continue at their occupation until they can exchange it for more congenial work and it is desirable to discover what the patient "would love to do" and try to point out ways and means of arriving at a practical solution of his problem. For instance, a person who had started on the study of medicine and who, because of family demands, has to make his living by "piece work" tailoring may have pointed out to him that his fatigue is really due to his dissatisfaction because of frustrated ambition. This individual's ambition may be guided into directions that are realizable and that will better satisfy his ego, as salesmanship or craftsmanship, most especially in a field akin to his ambition, such as the surgical instrument business.

Of course, a person who has been indolent and who, owing to lack of outside interests, has become largely

preoccupied with self is in need of the opposite kind of treatment, which has been pointed out under "occupation therapy"

SUMMARY

Psychoneuroses are due to the patient's inability to meet the situation of his life in an adequate manner. This inability is due to excess of external stress or a defect in the patient's constitution or, most commonly, the combination of the two. Treatment is therefore directed at (1) relieving the stress as much as possible and (2) remedying the patient's deficiency. The temporary removal of the symptoms of psychoneuroses is relatively easy. Permanent cure can be accomplished only by a change in the patient's personality by means of training to more adequate mental attitudes and habits.

The only excuse for inflicting this lengthy article on a literature-overburdened medical profession is that psychoneuroses are curable much more often than they are cured and that every doctor, no matter what his special line of work, has these cases and either helps or harms them in accordance with his understanding of their needs.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS

HOWARD A. CARTER, Secretary

REPORT OF THE COMMITTEE ON THE PRESENT STATUS OF PHYSICAL THERAPY

The original report of the Committee was written ten years ago,¹ at the time of the organization of the Council on Physical Therapy of the American Medical Association. At that time there were certain conditions in the realm of physical therapy that threatened its ethical standing with the profession as a whole. Many new pieces of apparatus had been introduced and many overenthusiastic statements had been made and published by those who were becoming addicted to an untried machine therapy. The original report sounded a warning concerning the abuses of physical therapy and then presented the Council's suggestions for an ideal relationship between physical therapy and other branches of medicine. The Council's predictions have been so nearly achieved and the status of physical therapy in the field of medicine today is so much improved and so firmly established on a sound basis that the Council now feels that a new report on the present status of physical therapy is necessary.

"Physical therapy" is the term employed to define the treatment of disease by various physical means. It comprises the use of heat, massage, exercise, light, water, electricity, and mechanical and other physical agents.

The use of these physical agents has become thoroughly established as an integral part of medical practice. However, knowledge concerning the exact physiologic effects, therapeutic usefulness and technic of application of many of them is still limited. Physical agents should not be used by the physician unless he is thoroughly familiar with the source of the physical

energy he is using and with the effects which it will produce. The use of these therapeutic devices empirically, simply to produce psychologic effects, is to be strongly condemned.

As in its previous report, the Committee desires to warn the profession as a whole against the acceptance of enthusiastic statements by manufacturers' agents—salesmen absolutely untrained in medical science. While the Committee feels that, for the most part, the sales agents of manufacturers of physical therapeutic equipment are no less trained and no more overenthusiastic than the representatives of many drug and surgical supply houses, nevertheless physicians are warned particularly against the high pressure type of salesman of physical therapy equipment who extols his device in terms of its earning ability. Choice of such devices should be based solely on the decision as to their therapeutic efficacy.

In its previous report the Committee pointed out that although physical therapy came into its legitimate place in medicine during the World War, it is one of the most ancient methods of therapy. At the time of this previous report, now several years ago, the Committee stated that physical therapy was gradually taking its place with the usual medical and surgical procedure. Today we may say that it has assumed its correct position in ethical medical practice and has become a definite part of modern medicine. The Committee desires to reiterate, however, that unless we guard against bad habits in its usage, against allowing it to replace careful diagnostic measures followed by well defined but less spectacular methods of treatment, and, especially, unless we guard against its insidious tendency to make its master an easy living, physical therapy may lead into dishonest practice or quackery.

The solution to the development of legitimate physical therapeutic practice has been found in the organization of the numerous departments of physical therapy in the hospitals of this country. Just as the physician, while he may do some of the simpler laboratory tests in his office, uses the clinical laboratory for more difficult tests, so does he utilize the hospital's physical therapy department for many of the more elaborate physical therapeutic methods of treating disease, even though he may desire to use some of the simpler physical therapy measures in his own office.

Among the physical measures that have been found both by clinical experience and by laboratory research to have certain therapeutic value when appropriately prescribed may be included (1) heat, in the form either of hot packs, hot water bottles, electric pads, radiant heat lamps, diathermy and short wave diathermy, hot baths, hot compresses, hot sprays and a number of combinations of electrical, radiant and hydrotherapeutic measures for producing heat or of artificial fever produced by hot air, hot water, high frequency currents and other physical means, (2) massage, such as stroking, kneading, percussion, friction and vibration, as well as stretching, pulling and corrective movements, (3) therapeutic exercise, including passive or relaxed movement, assistive movement, active movement, active resistive movement, corrective and therapeutic games and training in correct body mechanics, (4) hydrotherapy, including thermal packs, douches, sprays, baths, contrast baths, whirlpool and other special baths, under water exercise tanks and therapeutic pools, (5) radiant energy.

¹ Report of Committee on Present Status of Physical Therapy. J. A. M. A. 87: 1122 (Oct. 16) 1916.

either natural such as in heliotherapy or sunlight therapy, or artificial, such as is produced by air and water cooled mercury arc lamps, carbon arc lamps, radiant heat lamps, infra-red generators and other special devices for the production of various forms of artificial irradiation including radium and roentgen rays, (6) electricity in the form of galvanic, faradic and sinusoidal currents and high frequency currents (conventional and short wave diathermy), (7) mechanical measures utilizing pressure and suction machines and mechanical hydrotherapeutic and electrical devices, and (8) occupational therapy, both functional and nonfunctional forms, giving exercise by both diversional and purposeful types of work.

In its previous report the Committee stated that physical therapy was in a transitional stage and that it was "still violently condemned in toto by some physicians." Probably the best indication of the progress of physical therapy within the past few years lies in the fact that such a statement can no longer apply. There are few, if any, physicians who condemn physical therapy in toto in these days. The physician should no more condemn physical therapy in toto than he should condemn internal medicine, surgery, orthopedics or roentgenology in toto. While physical therapy is still in a transitional stage as far as its establishment as a recognized field of regular medical practice is concerned, nevertheless this transition has progressed within the past five years toward the point of complete consummation.

The Committee previously suggested that physical therapy should be considered as an adjunct to other forms of treatment, both medical and surgical. The Committee now wishes to suggest that, whereas physical therapy is a smaller and less developed field than either medicine or surgery, and whereas frequently the use of physical measures is merely an adjunct to other forms of treatment, it is possible to conceive of instances in which the use of some physical measure will be the primary method of treatment and medical agents or surgical procedures may be the adjunct. In other words, physical measures should be used only when and as indicated either primarily or secondarily in relation to other methods of treatment.

The previous report also dealt rather extensively with the use of physical therapy by charlatans and quacks. Our present report need not take so much cognizance of this angle. Nevertheless there are charlatans who practice in all fields of medicine and the idea should be abandoned that scientific physical therapy bears a stronger relationship to quackery than do other branches of medicine. The Committee feels that it must still sound a warning against overenthusiasm and exaggerated claims for the value of newly developed physical methods of treatment of disease. The present hyperenthusiasm concerning short wave diathermy and concerning positive and negative pressure machines is a case in point. At the present moment there is a trend toward overenthusiasm for the use of short wave diathermy and there is a similar wave of hyperenthusiasm for the use of positive and negative pressure machines in the treatment of circulatory diseases. Each of these measures appears to have a definite, though limited, field of usefulness, and each is being threatened with extinction because of the danger of a reaction against unwarranted claims. The

Committee desires to sound a plea for carefully controlled clinical studies on the use of such devices before results are published in the literature. Ethical manufacturers, it is hoped, will heed this warning and develop their devices on the substantial ground of scientific fact rather than haste to compete with a myriad of fly-by-night concerns.

At the time of the organization of the Council, overenthusiasm on the part of certain physicians concerning ultraviolet therapy, combined with the high pressure salesmanship of certain manufacturers, had literally swamped physicians' offices, hospitals and many private homes with all kinds of ultraviolet lamps, some effective and some worthless. It took the Council at least four years to clear up the ultraviolet situation. Finally, by rejecting many of these ultraviolet lamps and by listing the few diseases really benefited by ultraviolet, and by developing standards for advertising ultraviolet lights, this form of physical therapy was brought into its present ethical position. We must avoid overenthusiasm for all new physical therapy apparatus, lest we have a duplication of the ultraviolet fiasco.

In its previous report the Committee pointed out that "The Council on Physical Therapy feels that the following points must receive the most careful consideration of the medical profession: (1) Physics, physiology and biochemistry must be called on to dispel the empiricism of the past and to demonstrate scientifically the value of various physical agencies." The present committee is aware that there has been a great deal of work done in these fields during the past five years which has aided in dispelling the empiricism of the past but is still of the opinion that this point should be stressed. "(2) Physical therapy must be recognized as a definite part of medicine, to be practiced and controlled by graduate physicians. It should be used only as one of the triad of medicine, surgery and physical therapy. It should be prescribed only after careful physical and laboratory examinations of the patient have been made. It should never be prescribed except by a physician thoroughly trained in the use of physical agencies."

The present committee desires to elaborate this statement by suggesting that, according to present day conceptions, rather than occupying one corner of a triad, physical therapy is situated at one corner of a many sided geometrical figure bearing a relationship to all the medical specialties both major and minor which appear at the other corners of this figure. Further, the very fact that it does bear a relationship to so many of the medical specialties emphasizes its value to medicine as a whole. According to our present ideas the statement that adequate physical and laboratory examinations should be made prior to the administration of this form of therapy should be accepted by every modern physician and applies equally to all phases of medicine. Emphasis has been previously made that physicians should be thoroughly trained in the use of physical agencies. There is need, however, for further education in this field, not alone through the medium of the undergraduate medical schools, but also through postgraduate education at medical centers and through various medical societies and medical journals.

In its previous report the Committee stated "The treatment of disease, whether by drugs, surgery or

physical agents, belongs solely in the realm of medicine. A physician would not refer a patient to a non-medically trained technician for treatment through drugs or surgery, yet many physicians refer patients to technicians—masseurs, gymnasts or nurses who have not received training in physical therapy, or even to members of various cults for physical therapeutic treatment.

Therefore physical therapy must be recognized as a component part of medicine and patients requiring this type of treatment should be referred only to physicians trained in this specialty. In this way the use of these methods by charlatans will be largely eliminated."

The present committee desires to elaborate on this portion of the previous report by commenting that there are ethical technicians in the field who work in various hospitals and institutional departments under the direction of physicians, and occasionally as technical assistants to physicians specializing in the field. The Committee feels that just as ethical nurses work under the supervision of physicians and as laboratory technicians work under the supervision of a physician in charge of the laboratory, so well trained physical therapy technicians thoroughly imbued with medical ethics are logically of value in conducting the mechanical details of the administration of physical therapy under the supervision of a physician.

At this point the Committee desires to urge that all hospital departments of physical therapy be under the direction of a physician, and that the frequent practice of placing a medically untrained technician in charge of such departments be abandoned. The Committee realizes that the supply of well trained physicians in this field is limited, but it nevertheless feels that the rule should be adhered to in principle and that proper steps should be taken to provide the necessary graduate education in physical therapy for physicians. The technicians to serve under these physicians should be either graduate nurses or graduates of recognized schools of physical education, and in either case they should have had an additional year's training in a recognized school of physical therapy. The Council on Medical Education and Hospitals has prepared a list of approved schools for physical therapy technicians. The need for such technicians is manifest and their training should be encouraged, provided it is understood that they are to work under direct medical supervision.

The present committee concurs fully with the last portion of the previous report. "(3) Since physical therapy is a definite part of medicine, every medical school should give a thorough training in this subject. The paucity of postgraduate and undergraduate instruction in physical measures in our medical schools has placed the profession at a disadvantage. Many attempts have been made to remedy this situation. A subject as intricate as physical therapy requires more study than the acceptance of a salesman's assertion that the snapping of a switch or the pressing of a button will definitely assuage any pathologic condition.

"The making of physical therapists by courses of one or two weeks often reeking with commercialism must be condemned. The three to six weeks courses sponsored by reputable medical schools are frankly makeshifts but do serve to show the breadth of the subject at least they effect the realization that such a period suffices only for establishing the purely mechanical details of technique and the broader physiologic

groundwork on which, aided by his medical knowledge and common sense, one may attempt to erect a physiotherapeutic superstructure. The remedy is adequate instruction to undergraduates in the medical schools. Courses starting with biophysics should be given in the last three years. In the postgraduate schools more intensive and prolonged courses should be offered. Medical societies should invite physicians specializing in physical measures to give sane, scientific courses in physical therapy to the members. A fair proportion of the scientific programs of medical societies should be assigned for discussion of physical measures of treatment."

In commenting on this section of the previous report the present committee desires to point out that although the activities of the Council have practically wiped out commercial courses and that there has been considerable increase in the amount of postgraduate and undergraduate instruction in physical measures there is still great need for further development along these lines. The Committee on Education of the Council on Physical Therapy has aided considerably in the postgraduate instruction of physicians through the medium of various medical societies by providing a group of well trained speakers who are available to the chairman of any medical society's program committee. It has further increased the knowledge of the general practitioner by providing a series of monographs on various phases of physical therapy. These are available without charge for use by any ethical group of physicians. The fact that physical therapy is receiving more attention in the medical literature is obvious to any one who glances through the current journals or the *Cumulative Index Medicus* and compares these with a journal or a volume of the *Index* published five years ago. For example, in the April 4, 1936, issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION the words "physical therapy" appear in articles, announcements, committee reports, advertisements and so on no less than seventy-nine times.

In its previous report the Committee announced that the Council would "attempt to keep the profession informed of the extensions and limitations of therapeutic value of old and new methods and of the efficacy and danger of apparatus offered to the profession and the public by the manufacturers." The present committee desires to announce that the second edition of the Handbook of Physical Therapy, a collection of approved articles on various phases of physical therapy previously published under the auspices of the Council, is now available through the American Medical Association. It also wishes to bring to the attention of its readers a booklet listing the apparatus accepted by the Council on Physical Therapy. This will serve as a guide to the practitioner in the purchase of physical therapy equipment and may be obtained by writing the Secretary of the Council on Physical Therapy, 141 North Dearborn Street, Chicago.

The Committee feels that since its previous report the status of physical therapy in its relation to general medicine has improved considerably, that there is a better understanding of the field as a whole by physicians at large, and that the activities of the Council on Physical Therapy in its attempts to disseminate reliable information on this subject have been amply rewarded. There is still a need for even fuller cooperation between investigators and

sicians engaged in clinical fields, on the one hand, and, on the other, the small group of physicians trained in physical therapy who are attempting to place this branch of medicine on a more scientific basis

SANBORN MOTOR-GRATIC MODEL E-I-S METABOLISM TESTER ACCEPTABLE

Manufacturer Sanborn Company, Cambridge, Mass

The Sanborn Motor-Gratic Model E-I-S is a closed circuit motor blower, spirometer type of metabolimeter which weighs 67 pounds. This weight includes the water necessary for the mechanism, weighing 3 pounds, the table with oxygen tank, weighing 29 pounds, and the metabolism unit and all other accessories which go with the unit, weighing 35 pounds. It is 58 cm high, 22 cm wide and 40 cm long at the base. It has an extended size when in use of 86 cm high, 116 cm long and 22 cm wide. The entire machine is mounted on a sturdy base which can be conveniently leveled by two thumb screws at the motor end of the machine.

Oxygen to be breathed is contained in a spirometer 163 cm. in diameter supported in a water seal in the usual way. Soda lime used for absorbing the carbon dioxide from the patient's expired air is in a removable container within the spirometer.

A movable, upright support carries a solid wheel having two grooves of different diameters. One groove has a diameter of 11.2 cm and carries a chain by which the spirometer bell is suspended in the water jacket. The other groove is 8.2 cm in diameter and has attached a chain which lifts the marking carriage, to which the stylus or pen is attached. This solid wheel has an inner spring which counterbalances the weight of the spirometer bell and the marking carriage. The difference in diameter of the two wheels allows the spirometer bell to move 1.366 cm for every centimeter movement of the writing point. This reduction in movement allows the use of a smaller kymograph drum and paper of convenient letter size.

Two types of markers are provided and are interchangeable, one a metal stylus and the other a simple capillary type marking pen with a reservoir containing enough ink for several tests. Ordinary letter size paper may be used with the ink pen, but the metal stylus writes on special stylographic drum paper $8\frac{1}{2}$ by 11 inches in size, convenient for filing.

The kymograph drum is held in place and turned by a spindle projecting from a telechron electric clock mechanism in the base of the machine and is held at the top by a centering set pin which can be displaced to remove the drum. The paper is held in position by small clasps at both ends of the kymograph drum. The same switch is used for starting the clock and motor blower.

A metal encased 'red' alcohol thermometer is situated openly on the base of the machine in such a position that the bulb of the thermometer is in the flow of air going from the spirometer chamber to the patient. The use of colored alcohol makes the thermometer easy to read.

The blower for circulating the oxygen is mounted in a metal container, which with the motor forms a single unit. This is fastened solidly to a valve mechanism which is an integral part of the base, with openings direct to the spirometer chamber and to the outside air.

Two rubber tubes of 2 cm inside diameter lead from the valve openings to the patient. These tubes are held by a metal support of great flexibility, allowing them to be used in any desired position. A quarter turn of a small lever is sufficient to switch the respiration of the patient from the oxygen in the spirometer to the outside air.

When the machine is in use the patient breathes from a closed circuit in which the oxygen from the spirometer is circulated by the motor blower. This blower is placed in the return circuit and therefore draws the expired gas from the patient and drives it through the soda lime back into the spirometer. The negative pressure at the mouthpiece is less than 2 mm of water and the pressure at the outlet of the pump is slightly higher.

An ordinary small sized oxygen tank, an aneroid barometer, three rubber mouthpieces of the usual type, and the customary nose clip are provided with the apparatus.

Accessory rubber valves of the usual design are furnished with the machine to be used in case electric power is not available for driving the motor. These are enclosed in aluminum tubes, which can be inserted in the circuit between the spirometer outlets and the mouthpiece.

Tests of Mechanical Efficiency—The time clock mechanism turns the kymograph drum once in eight minutes. This is accurate to within two seconds and well within that necessary for clinical accuracy.

The spirometer bell volume was tested by the removal of definite amounts of air from the bell. The machine was found to be 99.8 per cent accurate, which is a variation of no clinical importance over such a short test period.

The machine was tested for leakage over several days' time with 175 Kg weight added to the bell and with 175 Kg lift on the spirometer bell. No leakage was found in any parts either with the motor running or stopped.

It was found that a pressure equivalent to a water column 3 mm at the top to 15 mm at the bottom was needed to move the spirometer bell from the highest to the lowest positions respectively.

The aneroid barometer furnished with the apparatus was compared with a standard mercury barometer and found accurate within the needed limits.

The apparatus was tested with the valves in place and found free from leakage. With a water manometer placed in the circuit it was found that a pressure change equivalent to 22 mm of water was required to operate the valves, while a change in pressure of 15 mm on each respiration was recorded without the valves and with the motor running.

The patient has a slight negative pressure to breathe against with the motor running while with the motor stopped and the valves in place there is a positive pressure against the lungs.

Basal Metabolism Determinations—This machine was tested by parallel basal metabolism determinations on patients in comparison with a standard machine of proved reliability. The results of a long series of such tests show an agreement of 1.7 per cent between these two machines.

Sanborn Motor
Gratic Model
E-I-S Metabo-
lism Tester

Table and Computations—The tables and charts used in the calculations have been checked and found to be accurate. The method of calculation is simple and time saving and the computation of the basal metabolic rate by these tables gives the same values as those computed by the Roth Metabolimetric Chart when the volume of oxygen is computed as 20.867 cc per millimeter drop of the bell.

Comparative Efficiency of the Valves and Motor Blower—As a result of the tests made with the valves and motor blower on the same individual under identical conditions as has been noted, further investigations of the comparative efficiency of the valves and motor blower on this machine were made.

By disconnecting the motor and inserting valves in the tubes connecting the patient with the spirometer chamber, the machine may be used without the mechanical circulation of oxygen.

The ease of operation as far as the patient is concerned when the valves are used compares favorably with other valve type machines. This is shown by the statements of the patients who used the machines in successive tests and by the comparative volumes of oxygen used during the tests. Patients also stated that the motor blower 'seemed to facilitate respiration' when compared to the Sanborn valve mechanism. The work caused by the valves was found to average 540 gram centimeters for each full respiratory movement of one centimeter by the spirometer bell.

In view of the favorable report, the Council on Physical Therapy voted to include the Sanborn Motor-Gratic Model E-I-S Metabolism Tester in its list of accepted devices.

RECENT INVESTIGATIONS ON STREPTOCOCCI

The relation of the ubiquitous streptococcus to specific disease processes is one of the most difficult problems in bacteriologic and immunologic research. The essential problem is how to differentiate the pathogenic from the nonpathogenic forms. Various methods have been studied with this aim in view, but thus far no thoroughly adequate method has been described.

A further attempt to advance the solution has recently been reported in a series of studies by Chapman and his co-workers.¹ The strains of streptococci used in their investigations were isolated from suspected foci of infection of patients with chronic diseases. After purified substrains were obtained, certain in vitro tests were applied. One of the earliest tests was the so-called bactericidin reaction, which was an attempt to correlate the resistance of streptococci to the "bactericidal" action of fresh, defibrinated guinea-pig blood. In the investigations reported other substances, notably sodium carbonate sodium bicarbonate, phenol, basic fuchsin, hexylresorcinol and merthiolate, were used in place of guinea-pig blood. Resistance to these chemicals was in many instances similar to that obtained with the blood. Because many of the strains of streptococci examined exhibited maximum resistance to the bicarbonate and hexylresorcinol solutions, attempts were made to measure higher degrees of resistance by including additional tests with stronger solutions of the same chemicals and with longer periods of exposure. A series of 1,898 strains was tested by exposing each strain to 0.3 per cent sodium bicarbonate for one hour and to 0.5 per cent sodium bicarbonate for two hours and testing for viability both immediately after mixing and again after exposure. Each strain was tested also by exposing it to 1:200,000 hexylresorcinol for one hour and to 1:125,000 hexylresorcinol for two hours

and similarly testing for viability. In 83.2 per cent of the strains the results were exactly the same with the two chemicals. In a further attempt to correlate the resistance factor with certain pathogenic factors rabbits were inoculated intravenously with strains of streptococci of differing powers of chemical resistance. A series of rabbits inoculated intravenously with streptococci that reacted negatively to the "bactericidin," hexylresorcinol and bicarbonate tests showed no apparent effects from the inoculation until a dose of at least 15 cc. of a culture had been given them. Those rabbits inoculated with chemically nonresistant strains died when the dose reached from 3.5 to 6 cc.

These results suggest that the types of streptococci studied possessed varying amounts of nonspecific resistance factor, which could be determined by exposure for adequate periods and in appropriate dilutions to a number of different chemical substances. Probably the nonspecific resistance factor may be measured quantitatively by exposure of the strains to certain chemicals. Furthermore, the experiments indicated that strains reacting positively to in vitro tests were able to kill rabbits in much smaller doses than strains reacting negatively to the tests.

A different method of attack has recently been reported by Longcope.² He examined for antistreptolysin 1,716 samples of serum from fifty-five supposedly normal persons and 516 patients suffering from a variety of disorders. From the results of these tests it seems justifiable to conclude, according to Longcope, that the upper limit of antistreptolysin in the serum from the normal adult is 100 units. The lower level in this series of normal adults was 12.5 units. It was also observed that the antistreptolysin varied little from month to month in the same individual. It appeared to be unaffected by severe colds and minor infection not due to hemolytic streptococci. Even a comparatively insignificant infection caused by hemolytic streptococci, however, might result in a significant rise in the antistreptolysin within eighteen days of the infection. In acute infections the number of slightly elevated antistreptolysin titers was somewhat greater than those obtained from normal patients. It is impossible as yet, however, to determine whether infecting organisms such as the meningococcus or pneumococcus are related to these rises. Several forms of hemolytic streptococcus infections also were studied. During the first few weeks of erysipelas there was usually a rapid increase in the antistreptolysin content of the serum. In scarlet fever, though the number of observations was scanty, there was a similar tendency manifested toward an increase in the antistreptolysin titer of the serum in the third week of the disease. High inter-

Observations on Patients Suffering from Streptococcal Infections. Pneumonic Fever and Acute Chronic Hemorrhagic Nephritis. *Id.* p. 27.

were also obtained regularly in one form of acute hemorrhagic nephritis but not in another form of the disease. Some correlation could be noted between the antistreptolysin curves and the course of the disease in patients with acute rheumatic fever and acute hemorrhagic nephritis. This correlation, however, was not close. Longcope advances the highly important comment that the high titers observed during the course of acute rheumatic fever and acute hemorrhagic nephritis indicate only that there has been a recent infection due to hemolytic streptococci and cannot be used as evidence that these diseases are caused by hemolytic streptococci. Finally, his observations indicate that there appears to be a difference of reactivity among persons suffering from different forms of streptococcal infection. This leads to variation in the production of antistreptolysin. Patients suffering from acute rheumatic fever and acute hemorrhagic nephritis appear to be especially prone to the formation of antistreptolysin in comparatively large quantities.

The investigations described indicate graphically the progress that has been made in the study of bacteria and the reaction which they produce since the time when practically all such research was based on morphology and cultural characteristics. Although the complicated problem of the streptococcus in disease is not yet solved, the advance in experimental technique foreshadows a hopeful outcome. Extension of observations along such lines as those carried out by Chapman and Longcope and further refinements in technique should eventually lead to clearer differentiation of this complicated group of organisms.

THE ANTISCORBUTIC FACTOR IN COW'S MILK

Because cow's milk has been relied on as the chief if not the only source of food for infants, and for many children and adults in ill health, the nutritive value of its many known constituents has received wide attention. Twenty-four years ago Frölich¹ demonstrated that cow's milk possesses antiscorbutic properties and his studies stimulated efforts to evaluate the amount of vitamin C contained in milk. Reports of such quantitative investigations have continued unabated since Chick, Hume and Skelton's² first indication that a daily consumption of from 100 to 150 cc of fresh cow's milk is needed to protect the guinea-pig from scurvy. In contrast to these and other similar observations there are reports which have claimed for milk a much higher antiscorbutic potency than was found by the English group. Wide variations in vitamin C values are due to a number of influences, some beyond the control of the consumer and some which he can regulate provided he has interest and knowledge. Partial

or complete loss of cevitamic acid (vitamin C) in milk is due chiefly, if not entirely, to oxidation, which may be induced by standing, by exposure to heat, light and air, and by the presence of metallic catalysts, especially copper. Nevertheless the experiments of King and Waugh³ have shown that the dairy industry may now produce pasteurized milk as rich in cevitamic acid as was the same milk in the raw state before pasteurization.

Milk as it is received by a dairy may vary in its content of cevitamic acid, owing to differences in the breeds of cows constituting the milking herds, their stages of lactation, and the rations which they are fed. Rasmussen and his co-workers⁴ determined the vitamin C in the fresh milk of cows "receiving a typical dairy ration which contained weighed quantities of green feed." They found that the average content of this factor in milk from Ayrshire, Guernsey and Jersey breeds is about the same but that milk from brown Swiss cows is richer in cevitamic acid and has an average value 48 per cent above that for Holstein cows, whose milk has the least potency. In view of the wide variations found in the milk from cows of the same breed, the suggestion was made that the stage of lactation may be a factor causing larger variations in the cevitamic acid content of milk than breed differences. Furthermore, the cow's ration may be an influence in determining the antiscorbutic potency of freshly produced milk. A recent report indicates that summer milk has more vitamin C than milk produced in winter,⁵ but other investigations have shown that a lowered content of cevitamic acid in winter milk is not necessary, for the various rations studied had no significant influence on the amount of this factor present.⁶

Fortunately, the consumer can be assured that the vitamin C content of raw milk supplied by a modern dairy can be practically constant throughout the year. In the interests of high milk production rations fed can be uniform and of good nutritive quality at all times. Pasteurized milk likewise can supply not only uniform amounts but as much of this essential vitamin as fresh milk.³ Hence the amount of cevitamic acid which the consumer may obtain from milk will depend in large measure on the methods of handling this food between the time of its delivery and its consumption. Serious losses in the antiscorbutic factor may occur in the home or hospital as the result of such simple procedures as mixing or decanting. A significant decrease in vitamin C has been reported³ in milk that stood from six to eight hours in the dark, even though it was cold. Reheating milk also lowers its potency, a loss of 20 per cent was observed after five minutes of light boiling,

but in heating milk an aluminum pan was as satisfactory as glass in conserving the cevitanic acid present. Nevertheless, the ordinary handling of milk in the home or in the hospital will inevitably cause some deterioration in its vitamin C potency.

The inherent nutritional virtues of milk have been vastly improved by modern contributions to the hygienic production and handling of this valuable food. The recent biochemical studies point the way to still further conservation of the nutritive values of milk.

CARBON TETRACHLORIDE IN INDUSTRY

The applications of chemistry to industry are prolific in creating new problems for physicians and pathologists. Among the earliest of the diseases of chemical origin were those due to lead and to carbon monoxide. Among the substances of wide use and high industrial value, carbon tetrachloride takes a foremost place. This liquid has properties of peculiar advantage. It is not only entirely noncombustible but also an efficient means of extinguishing fire. As a solvent and extractor of fatty substances, it has almost entirely displaced the highly inflammable naphtha and related liquids that formerly caused frequent fires with much loss of property and life in the cleaning industry and in homes. Against this advantage must be set the fact that carbon tetrachloride is a powerful and highly toxic anesthetic, its after-effects resembling those of delayed poisoning by chloroform. Carbon tetrachloride and chloroform differ in fact only in that the former is CCl_4 and the latter CHCl_3 . Like chloroform also carbon tetrachloride, in the presence of a flame or heated metal, forms phosgene, one of the principal toxic gases used in war.

Sanitary experts have for some years past increasingly emphasized the hazard to health and life involved in the use of carbon tetrachloride without measures to prevent inhalation of its vapor. The extensive industries manufacturing and using carbon tetrachloride were for a time resentful of what they regarded as attacks.¹ On this account Surgeon General H. S. Cumming three years ago invited representatives of the industry to meet those sanitarians who had been particularly outspoken in a conference in which the two sides were enabled to present their views. As a result of that conference the industries concerned themselves organized and gave the requisite funds to a committee appointed to study the problem and to report on practical measures for its solution. This committee then engaged Drs. H. F. Smyth, H. F. Smyth Jr. and C. P. Carpenter of Philadelphia to make a thorough experimental investigation and to report their results as a basis for regulations to control the health hazard in all branches of the industries using carbon tetrachloride.

The report of Drs. Smyth and Carpenter was completed a few months ago and its principal results and recommendations have now been published. It shows that no hazard to health is induced by concentration of carbon tetrachloride in the air breathed that do not rise above 100 parts per million, or 0.01 per cent. Now the industry has imposed on its members the requirement that in no plant shall the concentration of carbon tetrachloride to which employees are exposed be allowed to rise above this amount. This is certainly a method of solving a serious health problem which deserves approval by sanitarians and imitation by other industries having similar problems.

Current Comment

VITAMIN PROMOTION

For many years pseudoscientists have projected the idea of a perfect food substance that would contain all the essentials necessary for the diet in a single tablet to be swallowed by the human being three times a day and to obviate the necessity for meals of ordinary food. The idea is of course preposterous, unless the human body changes its anatomy in the near future. The stomach and the intestines require something more to work on than an ounce of pills three times a day. In the atrophy of disuse is not to affect the musculature, the requirement for bulk must be considered in the preparation of the perfect food. Moreover, the sense of taste and all the factors concerned in appetite constitute an important consideration in the selection of food. This, however, has not prevented manufacturers from offering to the public substances alleged to be almost perfect as foods. A new product is a so-called Vitamin Energy Bar, which is claimed to be the equivalent of three loaves of bread in fat, one pound of butter in protein, two and one-half pounds of cheese in carbohydrates, two bunches of celery in calories, two oranges in calcium, one large egg in phosphorus and four quarts of buttermilk in iron. Somehow the promoter overlooked vitamins F and H as well as zinc, manganese and copper. This is a fine example of the fallacy of equivalents as a standard of measurement. Instead of giving the equivalent in fat of the butter, the bread is chosen as the example, instead of giving the equivalent of the milk for calcium, oranges are chosen for that comparison. And the calories are said to equal those of two bunches of celery. 'Whoever picks celery for calories!' Actually the 'Vitamin Energy Bar' seems to provide one-half ounce of fat, one-sixth ounce of protein and less than 2 ounces of carbohydrate with traces of calcium, phosphorus and iron. That are the facts—but they do not sound nearly as impressive as the great quantities of food represented by the advertiser's equivalents. If however you really want to see if one 'Vitamin Energy Bar' is the equivalent of all that food eat the 'energy bar' at one meal and all the food at another. Your digestive system will solve the problem for you—and not mathematical!

Medical Economics

STATE EDUCATION AND STATE MEDICINE

The state educates us, why should it not heal us? It protects us against invasion, why not against disease? So runs one of the most frequent arguments for state medicine.

Perhaps the state system of education failed in its effort to teach logic to those who reason thus. Analogy is proverbially a dangerous foundation for a logical premise. Disease and education differ widely even though many exposed to both fail to get either.

For the special comparison, differences are greater than resemblances. Every one needs all the education he can get, especially if he is to be of value to a democratic state. In childhood and youth we all need much the same sort of education and even as adults there are so many who wish to learn the same things that books, lectures, classes and radio can be used effectively for mass educational treatment. It is possible to make fairly accurate diagnoses of ignorance and of progress through educational treatment by mass examinations, although even in education there are some doubts as to the accuracy and efficiency of such mass methods.

Ignorance does not come on suddenly and create an emergency demand for education. The need for education varies slightly with times and conditions. The positive benefits of education are not confined to the individual. Society obtains a direct return for its investment in the education of its members.

Health and ignorance are alike in only a few features and within those limits the state is already active. The value of that activity depends largely on how closely it is limited to the fields for which it is fitted. Whatever can be done for the people as a whole, the state can usually do with fair success. Where individuals must be distinguished and given widely different and suitable treatment, the mass action of government is seldom successful.

The state can establish quarantine to protect the whole people against the invasion of disease, collect and tabulate vital statistics of the whole population, assist in health education, urge widespread general immunization and rally the forces to meet the mass attacks of epidemics. Within those limits and such others as have the same qualities, the medical profession has always aided and encouraged state activity.

When individuals are to be aided in recovery from illness, the analogy with education becomes a contrast. It is seldom that two persons need exactly the same treatment. Medical service is seldom as helpful when given to groups or classes as when administered to individuals. The degree of disease and progress of recovery vary widely, are hard to measure and cannot be standardized in grades.

Medical service does not fit into time tables. Its value depends largely on a personal relation between two individuals—the sick person and his physician. It must be given in widely varying intervals to each individual, and its value depends in a high degree on the way it is suited to each personal situation.

The reasoning that would have medicine follow the educational pattern is further weakened by an increasing apprehension that standardization in education has not been wholly successful. Forcing teachers and pupils into a common mold is held to be destructive of both individual and social values, to injure those of exceptional ability and thereby to deprive the nation of greatly needed intelligent, independent leadership.

Political influence and pressure groups have worked much harm to education, although it is much better suited than medical service to resist or endure such influences. It is charged that supervision by lay boards ignorant of pedagogic methods, has hindered professional progress and tended to cripple the freedom of thought and investigation that is of fundamental importance in education. Again such influences would be much more destructive in the medical field.

In spite of the fact that education is freely offered by the state to every one and that over 26,000,000 pupils were in elementary and high schools in 1931-1932 there were at the same time over 2,700,000 in private and parochial schools. In other words, 10 per cent of the population refused to accept the

free standardized system offered and preferred to pay for the kind of education they considered more suitable to their individual desires.

The total cost of public day schools amounted to over \$2,160,000,000 and the expenditures in universities and colleges was over \$600,000,000 more. It was impossible even with these great expenditures and the enormous extent of standardization to provide employment for those who had been accepted as teachers, so that in 1930 there were nearly 12,000 teachers in the words of the census, "out of a job, able to work and looking for a job." The effect of the depression was widespread, causing reduction in educational services and failure to pay those teachers who still remained at their work.

To the extent that education does resemble medical service, it seems to have suffered under state administration. Only where the contrast is greatest has it been successful. If a comparison is to be made, it would seem to be a warning rather than as an example.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

A Large Malaria Prevention Project—A total area of between 20,000 and 30,000 acres in Greene County will be drained in a WPA project to reduce the prevalence of malaria in the state, newspapers report. In addition, about 2,000 acres of stagnant pools will be emptied. This program, the largest of its kind in the state, is said to be the only one in which the county has given financial assistance. Greene County officials have appropriated \$5,099 to supplement WPA funds of \$41,643.

ARKANSAS

Personal—Dr. Thomas M. Fly, Hot Springs National Park, has been appointed health officer of Little Rock to succeed Dr. Verdo T. Webb, who resigned to devote his time to private practice.—Dr. Thomas T. Ross, Arkadelphia, health officer of Clark County, has been appointed assistant director of the state department of health, in charge of the division of maternal and child health. He has been succeeded as health officer by Dr. Jesse K. Grace, Danville. Present plans call for the organization of a district health department, composed of Clark, Nevada and Hempstead counties, newspapers reported.—Dr. Silas C. Fulmer, professor of medicine, University of Arkansas School of Medicine, Little Rock, has been appointed assistant dean in the medical school.

CALIFORNIA

Society News—Dr. Newton G. Evans was chosen president of the Los Angeles Cancer Society at its first regular meeting, June 17. The next meeting of the society will be September 3.

Plague-Infected Squirrels—One squirrel received at the laboratory of the state department of health, July 7, from a point five miles south of Pine Creek, Modoc County, was found to be plague-infected, according to *Public Health Reports*. Evidence of plague was found in three collections of fleas received at the laboratory, June 25, from places within a few miles of Davis Creek, Modoc County. Plague was also found in five squirrels received at the laboratory July 2 from various places in Santa Cruz County.

COLORADO

Society News—A joint meeting of the Medical Society of the City and County of Denver and the Denver Radiological Club was addressed August 5 by Drs. John D. Camp, Rochester, Minn., on Osteoporosis and Its Importance in Medical Diagnosis, and James M. Martin, Dallas, Texas, on "The Physician's Responsibility to the Cancer Patient."—At a meeting of the Delta County Medical Society, June 26, Dr. John V. Ambler, Denver, discussed treatment of common infections of the skin.

The Colorado Medical Foundation.—At a meeting, July 8, the board of trustees of the Colorado State Medical Society approved the establishment of the Colorado Medical Foundation. The plan to organize the foundation was instituted at the 1935 meeting of the state medical society, when authority for its creation was granted to the board of trustees by the house of delegates. Its objective is to serve as a sound financial background for the membership of the state medical society and its income "shall be used exclusively for charitable or educational purposes and the necessary expenses incident thereto." Although the fund is now small, *Colorado Medicine* points out, it is provided that until the foundation reaches the sum of \$100,000, not more than 10 per cent of its net annual income may be turned over to the treasurer of the state medical society for expenditure. After it reaches \$100,000 and until it reaches \$1,000,000, up to 50 per cent of the net annual income may be utilized. After it reaches the million dollar figure, the portion of the income to be used, and the amount to be left in the fund to accumulate, will be determined by the officers and trustees of the society. The principal of the fund will never be expended. Any donor to the fund, however, may stipulate how his contribution may be expended and whether the principal and income shall be used in full or in part.

CONNECTICUT

Accidental Deaths.—Accidents accounted for 1,255 of 17,355 deaths reported in Connecticut in 1935. Of these, 491 were attributed to motor vehicles. In this group of accidents, collision with pedestrians accounted for 274 deaths. Of the 358 accidental deaths occurring in public places drowning was responsible for the greatest number, with a total of eighty-nine. In fatal accidents in the home, falls led the mortality with a total of 235, accounting for 67 per cent of the total in this group. Deaths due to occupation made up only 4.4 per cent of the total number, according to the state department of health, while accidents in the home accounted for 27.9 per cent and accidental deaths in public places for 28.5. With a rate of 39.2 per cent of all deaths, automobile accidents contributed more deaths than any other classification.

DISTRICT OF COLUMBIA

Personal.—Clarence J. West, Ph.D., for several years director of research information service for the National Research Council, has been appointed technical editor of the *Institute of Paper Chemistry* affiliated with Lawrence College, Appleton, Wis.

University News.—Dr. Henry Laurant Darnier has been promoted to clinical professor of obstetrics and gynecology at George Washington University School of Medicine, Washington, and Dr. John Edward Lind to clinical professor of psychiatry.

FLORIDA

Appointments to Health Positions.—The following appointments as district health officers have recently been announced in the newspapers: Drs. James W. McMurray, with headquarters in Marianna; Rayburn N. Joyner, Jacksonville, and Joseph S. Spoto, Ocala. Dr. Thomas E. Morgan, Jacksonville, has been appointed in charge of the newly organized health unit in Pinellas County, with headquarters in Clearwater, and Dr. Charles A. O'Quinn Perry, appointed in Taylor County.

GEORGIA

Society News.—Dr. James C. Metts was elected president of the First District Medical Society, July 15, and Dr. Charles Usher Savannah, was reelected secretary. The spring meeting of the society will be held in March. At a meeting of the Fulton County Medical Society in Atlanta August 6, Dr. George Hugh Cochran discussed "Brain Injuries" and Dr. James Gaston Gay, "Present Status of Surgery of the Thyroid in Children."

ILLINOIS

Division of Industrial Hygiene Created.—A division of industrial hygiene in the state department of health, Springfield, has been created to study health hazards under which employees work and make recommendations for preventive measures. Headquarters for the new division will be at the University of Illinois College of Medicine, Chicago, with Dr. Milton H. Kronenberg in charge.

Convalescent Polio Blood Serum Needed.—The state health department needs convalescent blood serum to replenish supply on hand for the treatment of new patients with

infantile paralysis. Healthy persons in Springfield and near-by who have recovered from infantile paralysis during the last few years and who wish to contribute blood for this purpose can be compensated. Additional information may be obtained from the state health department at Springfield.

New Building for Trachoma Clinic.—A new two-story building to house the trachoma clinic in Jonesboro was dedicated, July 15, under the auspices of the Union County Board. Speakers included Miss Audrey Hayden, secretary of the Illinois Society for Prevention of Blindness. The building was constructed with materials salvaged from abandoned country buildings, it was financed with WPA funds. Opened in 1934 in the Union County courthouse, the clinic is one of several in southern Illinois where trachoma is prevalent. More than 1,700 positive trachoma patients and 350 suspects attend the five southern clinics, which operate three days each week in Herrin, Harrisburg, Shawneetown, Vienna and Jonesboro, newspapers reported.

CHICAGO

An Eighty-Five Tops the Golf Tournament.—Dr. Frank S. Needham, Oak Park, won the VanDerslice Cup at the annual golf tournament of the Chicago Medical Society August 12 at Olympia Fields with a gross score of 85. First prize for low net score for officers and councilors went to Dr. Richard F. Greening, for branch presidents and secretaries, Dr. Anders J. Weigen. First low gross score for members was made by Dr. John P. Mulcahy, first low net by Dr. Guy V. Pontius. First high gross by Dr. John J. Gill. About 250 physicians and their friends participated in the tournament.

Dr. Visscher Goes to Minnesota.—Dr. Maurice B. Visscher, since 1931 professor of physiology, University of Illinois College of Medicine, has resigned to become head of the department of physiology and physiologic chemistry, University of Minnesota School of Medicine, Minneapolis, effective September 1. His successor at Illinois has not been announced. Dr. Visscher was a member of the teaching faculty at Minnesota from 1922 to 1925, when he took the degree of doctor of philosophy. He received the medical degree at Minnesota in 1931. He was a fellow of the National Research Council at University College, London, 1925-1926, after which he went to the University of Chicago. He served as associate professor of physiology at the University of Tennessee School of Medicine from 1927 to 1929 and of physiology and pharmacology, University of Southern California, 1929 to 1931, when he was appointed at Illinois.

INDIANA

Personal.—Dr. Thurman B. Rice, Indianapolis, has resigned as assistant director of the state department of health and has been succeeded by W. T. Frazier, Bluffton executive engineer of the department, it is the first time a layman has held the position. Dr. Rice will continue to act as director of the health and physical education department, a correlating department of the health and education departments created under the social security act. He will continue as editor of the department's bulletin. Dr. Maurice Joseph Barry was reelected president of the Indianapolis Board of Health and Drs. Clarke Rogers and Herman G. Morgan were reelected vice president and secretary respectively. Dr. Morgan will also continue as city health officer.

Dr. Wishard Retires.—Dr. William N. Wishard, professor and chairman of the department of genito-urinary surgery, Indiana University School of Medicine, Indianapolis, has retired, newspapers report. He has held this position at Indiana since 1887. He occupied a similar position at Purdue School of Medicine, retaining the title when the medical schools of the state merged in 1908 under the name Indiana University School of Medicine. Dr. Wishard, who is 84 years of age in 1879, graduated from Miami Medical College, which later became the department of medicine of the University of Cincinnati College of Medicine. He has been a member of his state and county medical societies since 1875 and served as president of the Marion County Medical Society in 1894. In 1895 he was president of the Mississippi Valley Medical Association and 1905 president of the American Urological Association and in 1918-1919 first vice president of the American Medical Association and member of its House of Delegates from 1912 to 1912. He was president of the Indiana State Medical Association in 1898. He served in various capacities in the association holding the chairmanship of the council from 1913 to 1913. He was chairman of the committee on public health and legislation of the state society from 1895 to 1922 and a member of the state board of health from 1909 to 1911.

president in the latter year Dr Henry O Mertz, clinical professor of genito-urinary surgery, has been named to succeed Dr Wishard. He is 52 years old and a graduate of Indiana, class of 1908.

IOWA

Twin Lakes District Meeting—Dr Thomas L Vineyard, Dow City, was chosen president of the Twin Lakes District Medical Society at the fourteenth annual meeting in Rockwell City, June 11, and Dr Paul W Van Metre was reelected secretary. Crawford County was added to the society this year, making twelve counties in the group. Calhoun, Carroll, Greene, Hamilton, Humboldt, Ida, Kossuth, Pocahontas, Sac, Webster and Wright.

Personal—Dr Tom B Throckmorton, Des Moines, was elected grand master of the Iowa Masonic Grand Lodge in Davenport, June 10-11.—Dr Regnar M Sorensen, Drakesville, has been appointed health officer of the newly opened health unit in Washington County.—Dr Paul Stephen, Cedar Rapids, has been appointed assistant in the division of communicable diseases and assistant epidemiologist, effective July 1. The appointment was made possible by social security funds.—Dr Arthur C. Schach, Burlington, has been appointed director of the reorganized health unit for Des Moines County, with headquarters in Burlington, effective June 1.

Society News—A program of antepartum service has been instituted in Washington County under the auspices of the state board of health and the county medical society, it is said to be the first undertaking of its type in rural Iowa.—Social security funds were used to finance a rural immunization program for children in Polk County, June 22-27, no charge was made regardless of the parents' ability to pay.—Speakers before the Austin Flint-Cedar Valley Medical Society in Waverly, June 11, included Drs Lee Forrest Hill, Des Moines, on "Serotherapy in Infectious Diseases" and Edwin J Kepler, Rochester, Minn., "Modern Treatment of Diabetes, Including the Use of Insulin Protamine." Dr William J McGrath, Elkader, was elected president.—Dr Edward B Hoeven, Ottumwa, was chosen president of the Des Moines Valley Medical Association at the sixty-third annual meeting, June 16.

LOUISIANA

Health at New Orleans—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended August 8 indicated that the highest mortality rate (19.9) appeared for New Orleans and the rate for the group of cities as a whole was 9.7. The mortality rate for New Orleans for the corresponding week of 1935 was 17.8 and for the group of cities 9.5. The annual rate for the eighty-six cities was 12.7 for the thirty-two weeks of 1936 as against a rate of 11.8 for the corresponding period of 1935. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area outside the city limits or that it has a large Negro population may tend to increase the death rate.

MASSACHUSETTS

Appointments to State Medical Board—Dr Charles P Sylvester, who was reappointed chairman of the Massachusetts State Board of Registration in Medicine, July 17 has resigned on account of ill health. Dr Royal Phillips Watkins, Worcester, has been named to fill the unexpired term. Dr Watkins was a member of the board from 1922 until the recent meeting when he was succeeded by Dr Harry L Stevens, New Bedford. Under suspension of the rules the council approved the nomination of Dr Watkins to fill Dr Sylvester's unexpired term, according to the *New England Journal of Medicine*.

Springfield's First Physician—A wreath was placed on the grave of Dr John E. Leonard, Springfield's first doctor, during the recent celebration of Springfield's three hundredth anniversary. Accompanied by Dr Henry E. Sigerist, William H Welch professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, members of the Hampden District Medical Society visited Dr Leonard's grave in the Agawam Village Cemetery, where a wreath was placed. Dr Leonard died in 1744, aged 69. A wreath was also placed on the grave of Dr Lambert Cooper, who died in 1755, as a tribute to Dr William H Chapin, Springfield, who is Dr Cooper's great-great-grandson. In the evening Dr Sigerist addressed a public meeting on "The History of the Development of Medicine 1636-1936."

MICHIGAN

Society News—Dr William J Butler, Grand Rapids, addressed the Eaton County Medical Society in Charlotte, June 25, on "Office Management of Genito-Urinary Disorders."—At a meeting of the Oakland County Medical Society in the St Joseph Mercy Hospital, Pontiac, June 16, Dr Irving W Potter, Buffalo, spoke on "Elective Version and Extraction."

Payment for Medical Fees Authorized—A monthly sum of \$50,000 is now available to pay physicians' fees for the treatment of crippled and afflicted children, as a result of action taken by the governor and the augmented state administrative board, July 22. All counties in the state have established a county medical society public relations committee in accordance with an agreement between the Michigan State Medical Society, the Michigan Probate Judges Association and the Michigan Hospital Association. Under this system afflicted and crippled children of the state will be examined and their economic status determined. Those able to pay will be "filtered" back to their family physician, physicians caring for children unable to pay will be paid with funds from the appropriation now made available.

MINNESOTA

Northern Minnesota Meeting—The Northern Minnesota Medical Association will hold its annual meeting at Fergus Falls, August 31-September 1, when the following program will be presented:

Dr Harold S Diehl Minneapolis The Medical School and the Practicing Physician
Dr James L McLeod Grand Rapids Acute Abdominal Symptoms Complicating Diagnosis
Dr William G Strobel, Duluth Pilonidal Sinus and Its Treatment.
Dr Virgil J Schwartz Minneapolis Dyspnea and Dysphagia of Unusual Origin.
Dr Owen H Wangersteen Minneapolis Significance of Anatomical Features of the Vermiform Appendix in the Genesis of Acute Appendicitis
Dr Edward B Tuoby, Rochester Recent Developments in Anesthesia
Dr Newton D Smith Rochester Hemorrhoidectomy A Plastic Operation
Dr Manley F Fellows Duluth Eyeground Examinations as an Aid to Prognosis in General Medicine
Drs Clement I Krantz and Thomas O Young Duluth Chronic Hyperthyroidism
Dr William A Stafne, Moorhead Recent Advances in Diabetes Mellitus
Dr Moses Barron Minneapolis Some Fevers Difficult of Diagnosis
Dr Charles S Randquist, Hibbing Sclerosis on the Iron Ranges
Dr Thomas A Peppard Minneapolis Symptomatology of the Various Leukemic States
Dr Maurice A Shillington St. Paul Interpretation of Heart Murmurs
Dr William F Merrill Crookston Missed Abortion

Dr William L Patterson and the staff of the Fergus Falls State Hospital will conduct a clinic on neuropsychiatry. At the banquet Dr Olaf J Hagen, Moorhead, will be toastmaster and William L Strunk Sc.D, professor of biology and chemistry, Luther College, Decorah, Iowa, guest speaker, on "The Vanishing Hosts." Dr Arthur N Collins, Duluth, will deliver his presidential address.

MISSOURI

Personal—Dr Warren H Cole, who has resigned as assistant professor of clinical surgery, Washington University School of Medicine, St. Louis, to become professor and head of the department of surgery, University of Illinois College of Medicine, Chicago, was honored by friends and colleagues at a farewell dinner, July 10. Speakers included Drs Evarts A Graham, James B Costen and Park J White Jr, all of St. Louis.—Dr Charles A. George has been appointed commissioner of health of Springfield.

NEW JERSEY

Death from Spotted Fever—A death from Rocky Mountain spotted fever was reported at Avalon July 18 according to the *New York Times*. The man became ill July 7. It was said that only eight cases have been reported in New Jersey in the past seven years.

NEW YORK

Chautauqua Medical Meeting—The fifth annual interstate medical meeting at Chautauqua under the auspices of the Chautauqua County Medical Society was held July 22. Speakers were Drs Byron D Bowen, Buffalo, on "Diabetes and the Use of a New Insulin," James G Carr, Chicago, "The Heart," William D Johnson, Batavia, "Surgery Now and Then," and Harry E Kleinschmidt, New York, "Progress in the Control of Tuberculosis."

Personal—Dr Edward S. Godfrey Jr., state health commissioner, and Dr Simon Flexner, New York, have been named members of an unofficial commission appointed by Governor Lehman to study Bang's disease and mastitis.—Drs Harry L. Chant, Hornell, and Edwin L. Crosby Jr., Schenectady, have been provisionally appointed assistant district health officers on the staff of the state department of health, assigned to the Hornell and Albany districts respectively. Dr Gordon R. Gray, Gouverneur, has been appointed assistant epidemiologist with headquarters at Amsterdam.—Dr James F. Michel, Farmingdale, celebrated his completion of fifty years of medical practice recently. Dr Michel is village health officer and president of the First National Bank of Farmingdale.—Henry D. Dakin, Sc.D., Scarborough-on-Hudson, received the honorary degree of doctor of laws at the annual degree ceremony of the University of Leeds, England, June 29. Dr Dakin took his doctor of science degree from Leeds in 1907.

State Tuberculosis Hospital Dedicated—The second of three new state hospitals for care of the tuberculous, the Homer Folks Tuberculosis Hospital at Oneonta, was dedicated July 9 with Governor Lehman the chief speaker at the ceremony. Other speakers were Drs Thomas Parran Jr., surgeon general, U. S. Public Health Service, former state health commissioner, Augustus J. Hambrook, Troy, chairman of the public relations committee, Medical Society of the State of New York, and Robert E. Plunkett, Albany, general superintendent of state tuberculosis hospitals, and Mr Folks. Dr Edward S. Godfrey, Albany, state health commissioner, presided. Mr Folks, for whom the hospital was named by special act of the last legislature, has been secretary of the State Charities Aid Association since 1893, with the exception of the two years 1902-1904, and member of the Public Health Council since its organization in 1913. He has also been president of the National Tuberculosis Association. The state legislature in 1931 authorized the establishment of three sanatoriums to serve rural districts. The first to be opened was the Hermann M. Biggs Memorial Hospital at Ithaca and the third will be at Mount Morris. Dr Ralph Horton is superintendent of the new hospital.

New York City

Hospital Moves Patients to New Location—Patients in the Manhattan General Hospital were moved from the old hospital at 161 East Ninetieth Street to its new location in the building of the former Lying-In Hospital at 307 Second Avenue July 26, the New York Times reported. The Lying-In Hospital merged with New York Hospital in 1929 and moved to that institution in 1932 leaving its building vacant. It has been completely renovated and has accommodations for 300 patients.

Hospital Department Official Retires—Dr Mark L. Fleming, general medical superintendent of the city department of hospitals since 1930, will retire October 1, having reached the retirement age. Dr Fleming was graduated from Cornell University Medical College in 1901 and has been associated with the city hospital service since his internship at Bellevue. For several years before he was named to his present post he was superintendent of Bellevue. Dr Sigismund S. Goldwater, commissioner of hospitals, announced that Dr Fleming would be appointed to the department's board of administrative consultants.

Laboratory Dedicated—Dr Isidore W. Held, clinical professor of medicine at New York University College of Medicine, was honored on his sixtieth birthday when the pathology laboratory at Beth Israel Hospital was dedicated in his honor. Dr Held is an attending physician at the hospital. Dr Nathan Ratnoff, medical director of the hospital, presided at the ceremony and speakers were Mr David I. Podell, president of the board of trustees, Justice Aaron J. Levy, a director of the institution, Dr John Wackoff, dean of New York University College of Medicine, Dr Emanuel D. Friedman, professor of neurology at the College, and Dr Meyer R. Robinson, attending gynecologist at Beth Israel.

Dr Lewis Appointed Director of State Psychiatric Hospital—Dr Nolan D. C. Lewis, professor of neurology at Columbia University College of Physicians and Surgeons and associate director of the Neurological Institute, has been appointed director of the New York Psychiatric Institute effective September 1. Dr Lewis is a native of Pennsylvania and took his medical degree at the University of Maryland School of Medicine in 1914. He was director of clinical psychiatry and director of laboratories at St. Elizabeth's Hospital, Washington, D. C., from 1923 to 1935 when he was appointed at Columbia. He was also professor of experimental

pathology at George Washington University School of Medicine from 1920 to 1924 and was appointed clinical professor of psychiatry in 1925. Dr Lewis succeeds Dr Clarence O. Cheney, who was recently made director of Bloomingdale Hospital, White Plains.

NORTH CAROLINA

State Board Meeting—The North Carolina Board of Medical Examiners will hold its next meeting November 1 at the Hotel Carolina, Raleigh. Only candidates for licensure by indorsement of credentials will be considered. Dr Benjamin J. Lawrence, Raleigh, is secretary of the board.

Society News—A group of papers on obstetric subjects was presented at a meeting of the Catawba Valley Medical Society, July 14, at the home of Dr John D. Rudisill, Lenoir, by Drs Williamson Z. Bradford, Charlotte, Abner M. Cornwell, Lincolnton, Glenn S. Edgerton and Henry H. Mennerick, Hickory.—Dr William S. Justice, Asheville, addressed the Buncombe County Medical Society, Asheville, July 13 on "Indications for Exploration of the Common Bile Duct."

Personal—Dr Hamilton W. McKay, Charlotte, has been elected president of the State Board of Medical Examiners.—Herbert C. Tidwell, Ph.D., formerly of Johns Hopkins University, Baltimore, has been appointed Grier research professor of biochemistry at Wake Forest College School of Medicine, Wake Forest.—Dr Thomas G. Faison, Winton, has been appointed health officer of Hertford County's new department of health.—Dr Wiley D. Forbus, head of the department of pathology at Duke University School of Medicine, Durham, has been elected a member of the National Board of Medical Examiners. He succeeds Dr Howard T. Karsner, Cleveland.—Dr William B. Hunter, Lillington, has been named health officer of Harnett County.

PENNSYLVANIA

Society News—The thirtieth annual meeting of the West Branch of the Fifth Council District of the Medical Society of the State of Pennsylvania was held at the York County Club July 16. Dr Francis C. Grant, Philadelphia, made an address on "Head Injuries and Spinal Cord Tumors." Dr Theodore B. Appel, Lancaster, "Maternal Mortality in the Fifth Council District," and Mr Ray Jansen, publicity director of the state society, "The Medical Society and the Press."—Dr Samuel Wolman, Baltimore, conducted a clinic on tuberculosis as guest of the Cambria County Medical Society July 9 at the State Sanatorium for Tuberculosis, Cresson.—Dr George W. Hawk Sayre, was elected president of the Association of Residents and Ex-Residents of the Robert Packer Hospital and Guthrie Clinic at a meeting in Sayre, June 2.—Dr John H. Musser, New Orleans, addressed the Lehigh Valley Medical Association at its fifty-sixth annual meeting at Pocono Manor, July 15, on "Abdominal Pain Due to Extra Abdominal Disorders."

Philadelphia

Medical College News—Sir David P. D. Wilkie, professor of surgery, University of Edinburgh Faculty of Medicine, Edinburgh, Scotland, will give a series of twenty-five lectures at Jefferson Medical College in November and December, the college announces.

TENNESSEE

Medical Society Protests Against Speeding Ambulances—The Memphis and Shelby County Medical Society recently adopted a resolution protesting against unnecessary speed in the driving of ambulances. A letter was sent to all ambulance companies in the city asking them to cooperate with the police department in making the streets safe. It pointed out that fast driving of ambulances was almost invariably unnecessary for the welfare of a patient and altogether unnecessary for both vehicle and pedestrian traffic. The society also tested against loud blowing of horns.

TEXAS

Personal—Dr John T. Moore, Houston, received the honorary degree of doctor of science from Texas Christian University, Fort Worth, at the June commencement.

Society News—The North Texas Medical Association held its annual meeting in McKinney, June 9-10. Addressers were Drs Percy M. Girard, Dallas, on "Prevention and Treatment of Ankylosis Following Trauma," and Tuck Sherman, "Treatment of Lobar Pneumonia by Artificial Pneumothorax." Charles W. Dunn, Dallas, "Management of

WEST VIRGINIA

WISCONSIN

tional program of the Rogers Memorial Sanitarium, Oconomowoc. Mr. Clifford W. Beers, New York, executive secretary of the National Committee for Mental Hygiene, was the speaker

CANAL ZONE

Lowest Death Rate—The general death rate in the Canal Zone in 1935 was 589 per thousand, the lowest in the history of the zone, it is reported. The decline from 7.52 in 1931 was attributed to absence of epidemic diseases and to the fact that new employees must pass a rigid examination

Society News—At a meeting of the Medical Association of the Isthmian Canal Zone in the Gorgas Memorial Institute, Panama, July 21, speakers were Lieut.-Col. Raymond A. Kelsner, Ph.D., Quarry Heights, on "Equine Osteomalacia", Dr. Mahlon Ashford, Balboa Heights, "Nature of Immunity to Malaria in Its Relation to Antimalarial Therapy," and George R. Callender, Balboa Heights, "Diarrheal Disease in the U. S. Army"

HAWAII

Territorial Election.—Dr. Lyle G. Phillips, Honolulu, was elected president of the Hawaiian Territorial Medical Association at the recent annual meeting. Dr. Douglas B. Bell, Dillingham Building, Honolulu, has been elected secretary

GENERAL

Cruise Postponed—A cruise planned for this month by the Latin-American Congress of Physical Therapy X-Ray and Radium has been postponed to March 1937. Sessions of the congress will be held in the National University of Medicine, Guatemala City, Guatemala. Dr. Norman E. Titus, 730 Fifth Avenue, New York, is president of the congress, Dr. Madge C. L. McGuinness, 1211 Madison Avenue, secretary, and Dr. Cassius L. de Victoria, 1013 Lexington Avenue, executive director

Warning—Fraudulent Salesman.—Two New Jersey physicians have recently reported activities of a man using the name D. A. Thomson and representing himself to be an agent of the "American Diathermy Rubber Co., Ltd., 329 Walnut Street, Philadelphia." He takes orders for goods, offering reductions for cash, and collects the money, but the goods do not arrive. Letters addressed to the firm name given are returned unclaimed and inquiry at the Philadelphia telephone company gave no information.

Society News—The second annual meeting of the Mississippi Valley Medical Society will convene at the Hotel Burlington, Burlington, Iowa, September 30-October 2. Dr. Harold Swanberg, 211-224 W. C. U. Building, Quincy, Ill., is secretary.—The Central Association of Obstetricians and Gynecologists will hold its eighth annual meeting at the Hotel Statler, Detroit, October 15-17.—The Inter-State Postgraduate Medical Association of North America will hold its annual assembly at the Public Auditorium, St. Paul, October 12-16. Dr. Tom B. Throckmorton, Des Moines, Iowa, is secretary

Premedical Honorary Fraternity—Alpha Epsilon Delta, national honorary premedical fraternity, celebrated its tenth anniversary at its annual meeting recently at Baylor University, Waco, Texas. The fraternity voted to use its influence to encourage premedical students to take a four year general course for a bachelor's degree as the best preparation for the study of medicine. It also recommended closer contact with the American Medical Association and other organizations concerned with medical education and adopted as a national project the promotion of general education in preventive medicine among college students. A chapter was installed at the University of Oklahoma after the convention, raising the number of chapters to seventeen. Only universities and colleges approved by the Council on Medical Education and Hospitals of the American Medical Association and members of recognized university associations are eligible to petition for chapters. The fraternity was founded at the University of Alabama in 1926. Emmett B. Carmichael, Ph.D., University, Ala., is grand president and Maurice L. Moore, Ph.D., New Haven, Conn., is grand secretary

Annual Report of Rockefeller Foundation.—During 1935 the Rockefeller Foundation expended \$12,725,439, of which \$2,733,050 was for medical science and \$2,200,000 for public health work. The major portion of the appropriation for the medical sciences was contributed to projects for the advancement of psychiatry. These included grants to the Institute for Psychoanalysis, Chicago, Johns Hopkins University School of

Medicine, Baltimore, Institute of the Pennsylvania Hospital, Philadelphia, Harvard Medical School and Massachusetts General Hospital, University of Michigan Medical School, Ann Arbor, University of Colorado School of Medicine, Denver and the University of Chicago School of Medicine. Fourteen research undertakings in clinical psychiatry and related fields were aided in the United States, England, Holland and Switzerland. Grants were also made to the National Committee for Mental Hygiene, New York, the North Carolina Commission for Study of the Care of the Insane and Mental Defectives, and the Massachusetts Department of Mental Diseases. Seventy-two fellowships in the medical sciences were administered during the year. The International Health Division sponsored studies on yellow fever, malaria, hookworm, tuberculosis, jaws, the common cold, diphtheria, influenza, typhoid, mental hygiene and smallpox vaccine in various parts of the United States and in numerous foreign countries. In addition, government health services were aided in many states and countries and advanced training in public health and public health nursing was made available to 188 persons. In the field of the natural sciences the foundation expended \$2,426,125, with most of the appropriations in experimental biology. These projects included research in universities in many parts of the United States, Canada and Europe on electro-encephalography, biologic effects of heat neurophysiology, cellular physiology, physiology of reproduction, the hormones and vitamins. Fifty-one fellowships in this field were administered during the year.

FOREIGN

Personal—Lord Dawson of Penn, physician in ordinary to King Edward VIII, was made a viscount in the list of honors conferred by the king on his forty-second birthday recently.—Prof. Hans Holfelder, Frankfurt-on-Main, and Prof. Alban Köhler, Wiesbaden, have been appointed honorary members of the American College of Radiology.—Dr. Etienne Burnet, formerly vice director of the Pasteur Institute of Tunis, has been appointed director to succeed the late Dr. Charles Nicolle. Dr. Burnet has recently been a member of the Health Section of the League of Nations.—Dr. Rene Sand, Paris, technical adviser to the League of Red Cross Societies since the World War, has resigned to become secretary general of the Belgian ministry of health. Dr. Sand is a native of Belgium.

French "Medical Days" in 1937—The standing committee of the "Journées médicales de Paris" announces a series of meetings to be held June 26-30, 1937, during the International Exhibition. The committee conducted similar meetings in 1926 and 1929. Physicians, pharmacists, veterinary surgeons, biologists, physicists and chemists of all countries are invited to participate. The subject selected for consideration is "Hormone and Endocrine Therapeutics." Mornings will be devoted to demonstrations in hospitals, schools and institutes of biology. Those who wish to attend are asked to write to Service des Journées médicales, Revue médicale française, 18 Rue de Verneuil, Paris 7.

Government Services

Vacancies in Navy Medical Corps

An examination for commission in the medical corps of the U. S. Navy will be held beginning December 1 to fill about twenty-five vacancies. The examination will be held at the U. S. Naval Hospital, Mare Island, Calif.; U. S. Naval Hospital, Great Lakes, Ill.; and the U. S. Naval Medical School, Washington, D. C., when examining boards will be in session. Candidates for admission must be between the ages of 21 and 32 years at the time of appointment, graduates of class A medical schools, and must have completed an internship of one year in a hospital accredited for interns by the American Medical Association and the American College of Surgeons. Further information may be obtained from the surgeon general, U. S. Navy Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

CORRECTION

"Snyder Products Co."—In THE JOURNAL, August 1, page 371, appeared an item relative to the Snyder Products Co. in which the cooperation of Dr. Louis Fishman with this company was emphasized. It should be pointed out that Dr. Louis Z. Fishman is not the physician concerned in this matter.

LONDON

(From Our Regular Correspondent)

July 4, 1935.

The British Medical Association and "Umckaloabo"

The council of the British Medical Association has been faced with a request from a lay body known as the Committee of Investigation on Treatments of Tuberculosis to investigate "umckaloabo," a substance also known as "Stevens Consumption Cure." The committee has obtained a sum of \$50,000 and proposes to equip a small home for the purpose of testing the treatment. The council of the Association was asked to advise and assist (1) as to the appointment of a resident medical officer at the home to keep cases under observation and make records; (2) to invite prominent physicians to form a committee to advise as to the types of patients to be admitted and to keep them and the home under observation. The council set up a special committee to consider the matter, and a joint meeting of this committee and the committee mentioned was held. The evidence for and against umckaloabo was summarized at this meeting and the method by which further inquiries might be prosecuted was discussed. The following memorandum was submitted by the council to the lay committee:

General principles are first laid down. It is the duty and desire of the medical profession to regard with attention any method proposed for the treatment of disease, from whatever source, provided there is scientific or empirical evidence which justifies some degree of reasonable expectation that the method may prove beneficial and is not likely to do harm. Every physician is free to use any method he believes to be for the patient's benefit. But the profession ought not to spend valuable time in testing clinically enterprises which have not adequate presumptive evidence in their favor. Many schemes of treatment once greatly vaunted have proved to be useless or even harmful. The medical care of a patient cannot be arranged as a pure scientific experiment; the patient's interest is paramount. But this does not mean that a new drug or method cannot be systematically studied, provided the interest of the patient, not the completeness of the experiment, is the deciding factor.

With regard to the particular proposal, the council of the association says that the financial support lent to it must receive cordial recognition as a humane desire to relieve suffering. Nevertheless any one who spends \$50,000 on an enterprise without reasonable expectation of success acts against the general interest, seeing that so many opportunities for service halt for want of money. The face value of the reports received by the lay committee is impressive, though they would need some expert scrutiny and unexpected recoveries from tuberculosis occasionally occur quite apart from administration of any drug. Existing opportunities for testing new methods are numerous. In the public tuberculosis service of the country under the control of the local health authorities are institutions where many recommended forms of treatment are tested. For example the Tuberculosis Service of Lancashire has recorded many investigations of this order, and if adequate justification can be submitted umckaloabo might be included. As compared with such a service already organized a new home or hospital would have obvious disadvantages. Assuming that not less than twenty beds would be adequate and that the experiment extended over three years the equipment and administration expenses would be considerable.

New Scheme for Research in Tropical Medicine

A new scheme of fellowships and appointments for research in tropical medicine is announced by the Medical Research Council on the advice of the Tropical Medical Research Com-

mittee, recently appointed after consultation with the colonial office. Three junior scholarships are offered immediately for award to physicians wishing to receive training with a view to careers in research work in tropical medicine. Preference will be given to candidates who already have had preliminary experience of research in some branch of medical science. Subject to satisfactory reports, the fellowships will be tenable for three years. The first year will be spent at the School of Tropical Medicine, the second in research work in the same or some other institution at home, and the third largely in work under direction at some center in the tropics. The stipends will be \$1,500, \$2,000 and \$2,500 in the successive years, with an additional allowance during service abroad and necessary expenses. The men who undergo this training will be eligible and well qualified for various appointments, apart from further employment under the scheme. At least one senior fellowship will be available for those who have held the junior fellowship. This will be awarded for three years at a stipend of from \$3,000 to \$3,750, with additional allowance during service abroad and expenses. The time will be spent mainly in research work in the tropics. The council is also prepared to consider applications for senior fellowships from candidates who have had adequate experience in research work, whether already trained in tropical medicine or not.

The council intends to establish in due course, as suitable investigators become available as the result of this scheme, permanent and pensionable appointments for research work in tropical medicine, including senior posts. Members of this research staff will work partly in the tropics and partly in institutions at home. The efforts of the Medical Research Council to this field have the support of the colonial office and the active cooperation of the schools of tropical medicine in Great Britain.

Prehistoric Surgery

At the Wellcome Research Institution Mr J. L. Starkey described the discoveries made by the Wellcome Archaeological Research Expedition at Lachish, about 25 miles southwest of Jerusalem. From the Lachish reliefs, found by Layard in 1854, in which contemporary artists showed the inhabitants of the city in great detail, it appeared that the Hebrews were the rulers of the city when it was attacked by Sennacherib in 701, B. C. After its destruction 1,500 bodies were thrown into a hole in the roof of a tomb chamber. From these bodies no fewer than 700 skulls have been recovered and are now in London awaiting scientific examination. It is hoped that they will give reliable information of the type of people living in Judah during the time of the Jewish monarchy and possibly show whether they were of purely Jewish stock or contained much of the original Canaanitish stock. Two of the skulls showed a remarkable form of trephining. Commonly that operation leaves a circular hole in the skull, but in the Lachish specimens the holes were cut square, a method previously known only in the Inca civilization of America. In one case the operator had begun to work on the right parietal bone but had completed the operation on the left.

The British College of Obstetricians and Gynaecologists

The regulations for admission to the membership of the British College of Obstetricians and Gynaecologists have been revised. When the original regulations were made, on the establishment of the college, the candidates were usually working in recognized hospitals and so were personally known to members of the council. But with the rapid development of the college and increase in application for membership both at home and from overseas, the examination has had to be reorganized. The guiding principle has been that it should be a test of sound clinical training and not, as so many examinations unfortunately are, a proof that the successful candidate is a

good examinee. The oral examination will consist of two parts: (1) a discussion of twenty-five selected obstetric cases attended by the candidate of which he has submitted records, (2) pathology. Applicants must have held resident appointments for six months in general medicine or surgery and for the same period in obstetrics and again in gynecology. Concurrently with this or separately they must have attended for six months at antepartum, postpartum and infant welfare clinics. Case records of ten gynecologic cases are required. The candidate will be asked to describe orally his treatment and his reasons for it. The cases must be vouched for as his own by a superior officer of the hospital. Commentaries—one obstetric and one gynecologic—not exceeding 2,000 words on one of the obstetric and one of the gynecologic cases, or preferably on a group of cases, must be submitted. The clinical examination will include a report on a selected case and an examination of other cases at the discretion of the examiner.

The Tragedy of a Surgeon

On May 22 Mr H. P. Nelson, specialist in surgery of the chest, pricked his finger with a diathermy needle while operating at the Brompton Hospital. The case was a clean one, but he had to do in the evening several dressings of other cases and from one of them his finger became infected. Next morning streptococcal cellulitis was evident and it spread so rapidly that his left arm had to be amputated. Unfortunately this failed to check the disease and he died June 24. He was only 34 and after the usual struggle was just beginning to ascend the ladder of surgical fame. Born in New Zealand, he was educated at Cambridge and at St. Bartholomew's Hospital, where he became demonstrator of anatomy and did research work. He was appointed instructor in thoracic surgery at the University of Michigan Hospital, Ann Arbor. Returning to England, he became chief assistant to Mr J. E. H. Roberts at St. Bartholomew's Hospital and assistant surgeon to the Brompton Hospital for Diseases of the Chest. He helped to found a surgical department at the Papworth Village Settlement and a special hospital for thoracic surgery under the London County Council. With Mr Roberts he published the first complete account in this country of the operation of pulmonary lobectomy. He was recently appointed assistant surgeon to the London Hospital. His abilities and character were greatly esteemed in the profession and there is no doubt that a great career has been cut short. A memorial fund for his widow and two children has been inaugurated by Lord Horder and other leading members of the profession.

The Blood Transfusion Service of the British Red Cross Society

The report of the Blood Transfusion Service of the British Red Cross Society shows that the calls on the London service during 1935 made a record, 4,701 calls were received, compared with 3,855 in 1934 and 3,017 in 1933. The growth of the service has been remarkable, for in 1925, when the British Red Cross Society took it over, there were only 428 calls. Thus in ten years the number has multiplied eleven-fold. On an average each donor serves twice per annum, and in 1935 the resources of the service were strained to the utmost. One factor in the increased calls was the introduction of drip transfusion, originated by Drs. Marriott and Kekwick of the Middlesex Hospital, which allows the introduction of the corpuscular content of from 8 to 10 pints of blood by means of a steady drip, the process taking two or three days. The effects have been so successful that other hospitals are using this method. Though every effort is made to obtain donors from relatives and friends of the patients, a heavy burden has been imposed on the transfusion service. During the year 222 night calls were received, between 11 p. m. and 9 a. m., compared with 174 in 1934. Two donors have now served on more than sixty

occasions while 619 badges have been gained by donors who have given ten or more transfusions. An analysis of the active list shows that the members have on an average 891 transfusions to their credit. The serum agglutinins of every member are carefully checked. At the International Blood Transfusion Conference, held in Rome last September, the Belgian delegate, Dr. Anet, said that the initiative of the British Red Cross Society in its transfusion service had served both as a model and as an inspiration for the creation of similar services throughout the world.

Decline in Syphilis in England

Speaking at a meeting of the British Social Hygiene Council, Sir Kingsley Wood, minister of health, said that any compulsion in the treatment of venereal disease was likely to defeat its own end. Results generally were improving. Efforts made in the last twenty years to educate the public had resulted in a more general realization of the dangers and of the importance of seeking medical advice at an earlier date. The incidence of syphilis was on the decline. Recent infections dealt with at the treatment centers in 1935 were just under 6,000, as compared with over 9,000 in 1925, while the mortality of syphilis in infants in 1934 was less than half what it was in 1924, and about a sixth of the mortality in 1917.

Involuntary Dyeing of the Hair

Two dermatologists, Drs. A. M. H. Gray and R. A. E. Klaber, have described in the *British Journal of Dermatology* a manner in which the hair may become dyed that has received no attention in the textbooks. A woman aged 50, gave much attention to her silver gray hair. She had it cut, washed and water waved at frequent intervals. For some want of profusion after an accident her physician prescribed a lotion, which she used daily and then discontinued as it took the wave out of her hair. During the next three weeks she had the hair shampooed prior to a permanent wave. According to the usual practice the hair was treated with an ammoniacal spirit lotion before being curled and placed in the heating tubes. When the hair was removed from the tubes a striking change was observed. Except for the extreme front and back and the proximal one or two inches of each hair the whole was diffusely dyed. The color was brownish black in front fading gradually to light brown behind. Hydrogen peroxide failed to bleach the color. Microscopic examination of the dyed hair showed a uniform brown coloration with absence of pigment granules. Chemical investigation showed that this pigment was mercuric sulfide. It was found that the lotion prescribed by her physician contained a grain of mercuric bichloride to the ounce.

Mercury is among the metals the salts of which have been used in progressive hair dyes. For this purpose subsequent application of heat or of a sulfur compound is necessary. Thus in the McCall Anderson formula a 1 in 250 solution of the bichloride is followed by a 12.5 per cent solution of sodium thiosulfate. A similar case has been reported by Philipsen (*Ugeskr. f. Læger* 95:746 [June 29] 1933). In both cases it was clear that the dyeing was dependent on combination of the mercuric salt with sulfur, presumably derived from cystine content of the hair keratin and that the reaction required the high temperature used in the permanent waving. A similar case has been reported in America by Dr. C. J. White of Boston (*New England J. Med.* 214:708 [April 2] 1936). A white haired woman who allowed herself one permanent wave a year was annoyed because on the last two occasions her hair turned a slate color and her friends would think she was foolish enough to have her hair dyed. Dr. White adopted the explanation just given though it was not actually proved that she used a mercurial lotion. The dye did not yield to any decolorizer which he dared use on her delicate hair but time restored the normal color.

PARIS

(From Our Regular Correspondent)

July 13, 1934

The Ninth Annual Pediatric Congress

This year's meeting was held May 28 at Bordeaux under the presidency of Prof. Charles Rocaz. Pediatricians from foreign countries, including the United States, took part in the program.

In a discussion of the insulin treatment of infantile diabetes Professor Aubertin of Bordeaux stated that all cases of diabetes in infants and children presented clinically a progressive excretion and that insulin treatment should be begun as early as possible. Since insulin permits the child to metabolize the necessary quantity of food, it is essential that such an amount of nourishment be given as the child requires. A simple rule is to give 1,000 calories for a child 1 year of age and 100 calories for each additional year. The proportion of proteins that is most convenient to order is 15 per cent of the total ration in calories during the first five years, 12 per cent for children between 5 and 10 years of age and 10 per cent between the ages of 10 and 15 years. During the early period of insulin therapy a diet poor in glucides (from 20 to 25 per cent of the total calories) and rich in lipids (from 65 to 70 per cent of this diet) was given. In time, the glucide tolerance gradually lessened. Hence a modified diet is in use at present which is rich in glucides (50 per cent of the total calories) and poor in fats (from 35 to 40 per cent of the total calories). It is more difficult to control the diabetes at the beginning of the treatment, but later an appreciably increased tolerance is observed. The establishment, fractioning, spacing and distribution of the doses of insulin ought to be adjusted according to the reactions in the daily variations and the effect of different foods on the blood sugar content. The regulation of the dosage is governed primarily by the examination of the urine after each dose of insulin and secondarily by the blood sugar content at various intervals of the day. Muscular exercise acts as a valuable aid to insulin. As to the complications of insulin therapy in children, inflammatory reactions are rare and not serious. Complications due to intolerance are seldom observed at present, because of the better technic employed in the preparation of insulin. Diabetes is seldom observed in children less than a year old. Above this age the prognosis is unfavorable in spite of insulin therapy except in certain cases in which the disease is transitory.

The acute infectious diseases do not affect diabetic any more seriously than nondiabetic children of the same age. It is essential to give the same total number of calories with decreasing either the glucides or the doses of insulin. In fact the latter should be increased because of the appearance of a certain degree of insulin resistance. Operative intervention thanks to insulin can be carried out as safely in diabetic as in nondiabetic children. Diabetic coma if treated promptly is less serious in children than in adults, unless complicated by some infective process.

With insulin therapy and an adequate diet growth is not interfered with. Cure of the disease is exceptional but it frequently sees a marked improvement in tolerance especially if a diet rich in glucides is given. In many children treated with amounts of insulin are indicated for two or three years less the diabetes may be subject to inexplicable exacerbations in spite of apparent control of the disease. Such exacerbations occur, however more frequently in children who have been insufficiently treated.

The mortality from infantile diabetes is about 2 per cent in centers in which adequate treatment can be carried out. Forssell has reported a mortality of 67 per cent in Finnish rural districts where proper care was lacking.

Insulin in Nondiabetic Conditions in Children

In discussing the subject of insulin in nondiabetic conditions in children, Marcel Lelong of Paris first took up insulin therapy in nurslings, which renders valuable aid in the treatment of denutrition of the second degree and even in advanced cases, as follows (1) in cases of anorexia if the latter is secondary, i. e., not the result of some organic cause (infectious or other), (2) when the difficulty of water fixation plays an important part in the inability to add weight, (3) when, and this is infrequent, disturbances of glucide metabolism exist.

The contraindications to the use of insulin are 1 A fall in the initial weight of the new born, here the use of insulin is dangerous 2 In denutrition syndromes of definitely organic origin, here it is more important to treat the underlying (infectious, alimentary, digestive) cause than to treat the symptom of denutrition 3 In true denutrition (athrepsia), in which insulin is of no avail 4 In denutrition conditions when edema is present

Accidents due to insulin therapy are not to be underestimated. Fortunately they are mild (sudden pallor, profuse sweats, feeble and rapid pulse) but cases in which convulsions occur have been reported. The important fact to bear in mind is that as the result of the glycemia equilibrium in infants, such accidents cannot be foreseen.

Insulin therapy in nurslings calls for a diet rich in carbohydrates. It is necessary that the insulin hypoglycemia should be counterbalanced by the alimentary hyperglycemia. Only small doses of insulin can be used, a clinical unit per kilogram a day, in one or two subcutaneous injections. Carbohydrates can be given by mouth or by the parenteral route. A good rule is to assure a minimum of 3 Gm of dextrose per unit of insulin. The duration of the treatment is variable. A safe method is to use insulin for two or three weeks and then discontinue it for an equal length of time.

In infants, insulin therapy encounters greater obstacles than in nurslings. The usual dose is from 10 to 15 units a day with each of two feedings, the latter to contain an ample amount of carbohydrates. Insulin therapy does not exclude the necessity of rest and of a good general and alimentary hygiene, as well as open air life.

In general, Lelong considers insulin of secondary importance in nondiabetic conditions in children.

Lereboullet and Gournay of Paris have followed, since 1921, thirty cases of infantile diabetes in the hospital with three deaths and thirty-five cases in private practice with fourteen deaths, the latter being due to the fact that treatment was more difficult to carry out outside the hospital. Fifty-seven per cent were boys and 43 per cent girls. The real influence of both syphilis and tuberculosis have not as yet been sufficiently taken into consideration. In one infant the diabetes appeared two months after an attack of mumps and one month after an acute pancreatic syndrome. In four children the diabetes was of the renal type. When an infantile diabetes is correctly treated, the insulin is well tolerated. Death is usually the result of discontinuation of the insulin therapy, lack of supervision of the diet and intercurrent disease. Education of the parents is essential. The same is true of frequent urinary and blood examinations in order to act as a guide for the doses of insulin.

Professor Fanconi of Zurich, Switzerland, reported fifty cases in which very satisfactory results were obtained with a diet containing little albumin and fat, with a base of fruits and vegetables.

EPIDEMIOLOGY AND PATHOLOGY OF INFANTILE ACRODYNIA

The subject of the second symposium was the epidemiology and pathology of infantile acrodynia. In France the term acrodynia has been adopted to designate the syndrome of an epidemic disease which affects children from 6 months to 7 years of age, rarely later than that period. At times it is

encountered in adults. It begins by irritability, digestive disturbances and a tired feeling. At its height, pains are complained of in the extremities, accompanied by changes in sensation, paresis, psychic disturbances with rapid regression of the intelligence and finally trophic changes involving especially the flexor aspects of the extremities, and the condition may terminate in a mutilating gangrene of the fingers and toes. The duration of the disease is about six months, but complete recovery is the rule.

It seems to have first appeared in northern Germany in 1898 but its existence has been reported in nearly all parts of the world except the Scandinavian countries, the majority of cases being observed in the winter and spring. Whether the disease is contagious or not has not been established, but isolation of the child for a period of several weeks is certainly advisable. The relation to other infections such as influenza, poliomyelitis and encephalitis is not clear at present, but it would appear as though there is little if any connection between these diseases and infantile acrodynia.

In the discussion, Mouriquand of Lyons reported several cases in children living in the same or adjacent houses but in which there had not been any apparent contact. In four necropsies, unquestionable lesions of the neurovegetative system were found especially at the level of the cervical and dorsal sympathetic ganglions. Rabbits inoculated by the cerebral route all died within one or two months after presenting paralytic symptoms.

Beutler of St. Etienne said that he had observed 102 cases since 1925 and in addition, twenty-four cases had been verified by others in adjacent counties. They seemed to bear no relation to other epidemics or to whether the child was living in a large city (fifty-three of the 102 cases had occurred in St. Etienne) or in a rural community. Sequelae such as more or less important mutilations, decalcification of bone and a neuropathic state had followed in some children. Two similar familial examples of contagion were cited, hence physicians should report cases of infantile acrodynia. Béraud of La Rochelle reported twenty-nine cases, of which fifteen were in an area 28 miles in circumference. There seemed to be no true epidemic, but sporadic foci.

Drastic Changes in Control of Advertising

Numerous attempts to place the advertising of therapeutic aids on a sound basis have been reported from time to time. Now that a decree of the Advertising Council of German Economic Life has been issued, the diverse and unsatisfactory control exercised by the individual German states has been swept away. Specific provisions now cover the material, style, methods and inspection of advertising, and their observance will be enforced by the police. The new laws concern therapeutic aids in the broadest sense of the term, this means not only the advertising of medicaments properly speaking but that of therapeutic procedures and methods as well. All types of advertising are included, even of a relatively private nature. Medicaments are defined according to the new statute as "substances which are designed to prevent, palliate or eradicate sickness, pain or bodily injuries of any kind whatever in man or beast." Further provisions cover agents of local or general anesthesia such as are employed for alleviation of labor pains, diagnostic aids, remedies for senile phenomena, especially somatic and psychic conditions, aids to rejuvenation, aphrodisiacs, aids in overcoming habitual use of alcohol and tobacco and finally foodstuffs, food preparations, cosmetics and disinfectants so far as the definition of medicaments may apply to these. The catalogue of substances of which the new law takes cognizance is inclusive indeed.

The illegality of 'misleading advertisements' is given a prominent place in the law. Deceptions, according to the

wording of the statute, may be of different sorts false statements concerning the composition of a substance or the condition and quality of an appliance, attributing to substances exaggerated and nonexistent virtues, or propaganda calculated to create the false impression that successful results may be regularly, certainly or in all probability anticipated from the use of a substance or that such a substance may be successfully used for a variety of diseases. It is deemed a deception if false statements are made concerning the education, qualifications or professional standing of the advertiser or if the impression is created that testimonial statements are being furnished disinterestedly. Any advertising is held illegal which on investigation is found to involve the treatment of contagious diseases by the patients themselves or by persons other than physicians, this applies also to the treatment of venereal diseases or of dysfunctions of the genitalia. Further prohibited is the offering of absent treatment and any advertisement that creates a fear of impending death or otherwise evokes anxiety and apprehension. No advertisement of a substance for which a prescription is legally necessary shall circulate among the public, and the same applies to any advertising of substances and appliances purported to prevent, palliate or eradicate disease caused by malignant growths or infectious diseases (including tuberculosis) the reporting of which is compulsory. The advertising of substances and appliances designed for the amelioration of venereal disease or for the prevention or interruption of pregnancy is confined to physicians, pharmacists and specially licensed business concerns. For the advertising of medicaments to be used during pregnancy, special approval is required for each substance. The same rule applies to procedures and treatments for pregnant women. Substances listed in the Secret Catalogue of Medicaments must not as a rule be publicly advertised.

Recommendations and testimonials can be used only with the express written consent of the person in question and must take the form of a precise, dated, personal statement. Testimonials for which compensation of any sort is given or promised cannot be published. A recommendation that takes the form of advice may be published or mentioned only if the author is a professionally qualified scientist and specialist, and in such cases a precise personal statement must be obtained. The testimonials of specialists must be clearly separated from those of laymen in the advertisement. Of great significance is the stipulation that, if any passage from the literature is cited in the advertising, there must be no confusion as to whether such citation relates to the general topic or is a specific reference to the substance in question.

A special administrative board has been formed which exercises control over all medical advertising. This board may impose further restrictions on the advertising of certain substances or of the treatment of certain diseases and on the form of propaganda employed with special relation to the display of laymen's testimonials. Any advertisement may be submitted to a competent authority for approval before permission to publish is granted. The board may forbid wholly or in part whatever it considers out of harmony with the law.

All these regulations become effective August 1. Violators are liable to fines not to exceed 150 reichsmarks and to imprisonment. The new legislation certainly represents a great step forward. Many abuses in the field of medical advertising will doubtless be removed. A perusal of the advertisement sections of the professional medical journals will convince any one of the deterioration that medical advertising has undergone in recent years. All too frequently one runs across medical advertisements in which the ingredients of a product are either inadequately described or what is more common not described at all. And this omission is usually accompanied by the most extravagant claims of therapeutic efficacy. The advertising or

certain substances and firms which was formerly a good reason denied space in the columns of reputable journals has somehow obtained entrée and frequently assumes a most obtrusive form. Since it is generally known that doctors may be completely taken in by the psychological use of clever advertising propaganda of medicaments, the new legislation is calculated to effect a drastic purgation of the professional as well as the popular mediums.

Reform of Pharmacy Under the Third Reich

The government has undertaken an incisive intervention in the activities of pharmacists and pharmacies which parallels its attempt to regulate all other fields of public health. Some time ago new legislation with regard to examinations was instituted, by which the course of university training for pharmacists was increased to six semesters. Prospective pharmacists now receive a wider scientific background and a greater opportunity for postgraduate study and accordingly will be better able to meet the more exacting demands of present-day research and practice. These reforms were indeed timely. Large numbers of pharmacists have long been unemployed and two remedial measures had been calculated to aid them: first, admittance to the courses for career pharmacists was temporarily stopped and, second, the employment in pharmacies of so-called women assistants (helferinnen), or at least the performance of pharmaceutical duties by such women, was prohibited. Formerly, while well over a thousand trained pharmacists were unemployed, many female assistants ignorant of pharmacy were able to obtain jobs and these women worked for half the stipend of a pharmaceutically trained employee. But such assistants could act only in purely mechanical capacities and hence were considered as salespersons.

Female assistants can now function only as bookkeepers and cashiers. After the new law went into effect the number of unemployed pharmacists rapidly decreased. The closing of professional study to prospective students was later mitigated by the installation of a numerus clausus, but still only ten pharmacists, some 5 per cent of the total number, have the right to train a praktikant (Praktikanten are pharmacy apprentices, each prospective pharmacist must prior to beginning his university training have worked for a certain time as a praktikant, if he is unable to do so because of the numerus clausus, he will not be permitted to begin his studies). This quota represents specifically the maximal number of the new generation who can hope in the future, in view of the existing demand for approved pharmacists, to find the opportunity to make a living in the profession within a certain time.

Noteworthy innovations also were effected with regard to the licensing of pharmacies, without a permit in due form a new pharmacy can be opened or an existing shop continue to do business. Such licenses are not granted non-Aryan pharmacists and this law applies to the entire Reich. It is no longer possible for any non-Aryan to acquire an apothecary shop. But the provisions of the more recent legislation go even further: there are clauses governing the renting and operation of public pharmacies according to which in case the pharmacist-proprietor is legally prevented from carrying on he must transfer the operation of the shop to a legally qualified pharmacist as lessee. The choice of a lessee is virtually free but is subject to the approval of the board of control. A pharmacist's widow for example can no longer rent a pharmacist-manager who thus would become the employer of an untrained woman. By the new national renting law the lessee is assured an independent status: he may not run a pharmacy must likewise be leased if through the expiration of the incumbent the normal purveyance of pharmacy supplies to the public is in any way endangered.

proprietor is unfit to carry on because of national or moral considerations or is hampered in the conduct of his business by the infirmities of age, insanity, drug addiction or some other permanent disability. Jews are specifically barred from the operation of pharmacies. Pharmacies the proprietors of which are Jews come under the "compulsory leasing clause." Accordingly, a Jew is in any case prevented from the operation of a pharmacy even if it is his own. As an official comment on the new legislation has it, "Jewry's last hold on the German pharmaceutical profession has herewith been broken."

The Program of the Hungarian Cancer Committee

At the annual meeting of the Association of Scientific Societies of Hungarian Physicians, Prof. William Manninger read a paper about the campaign of the Hungarian cancer committee. Unfortunately the committee at present cannot hope to complete its program because the state cannot provide the funds that would be necessary. The financial condition of the state was responsible also for the fact that the state tumor hospital and research institute had to be closed.

The new cancer campaign mapped out by Professor Dollinger is much more modest, and the chief obstacle to its achievement is not the want of money but the want of knowledge of the cause of cancer. According to present knowledge, cancer is not the result of a single cause but the sum of many conditions. The Hungarian Cancer Committee is not prepared to carry forward a campaign of treatment. The aim of the committee is to offer means for the demonstration and criticizing of the individual's work and of the results achieved by various methods.

The Dollinger plan consists of four main points: 1 To keep functioning all those research institutes which are dealing with biologic problems. To build in all parts of the country subsidiary centers where intensive research will be done on the histology and physiology of cancer. The equipping and maintenance of the institute is the duty of the state and municipalities. Finally, to compile cancer statistics based on strictly scientific control. Almost all parish and village doctors have offered their services to fill out the statistical blanks. 2 The committee intends to provide the country hospitals with physicians versed in the treatment of cancer. The use of auxiliary methods of treatment, including radiation therapy, is impossible on account of the lack of radium and of funds to meet the costs. It is the task of the committee to provide funds. The committee will persuade the government to establish a central institute in Budapest equipped with all recognized means of treatment. This institute is to maintain a close link with the university and also with all physicians interested in the cancer problem. The committee will distribute free books to all physicians of the country to aid them in the recognition and treatment of cancer. A further task of the committee will be to arouse the government to establish in every county laboratories equipped for the early diagnosis of cancer and also for the treatment of cancer. A special cancer library, at present consisting of 1,700 volumes, is at the disposal of all those physicians who are interested. 3 The committee will give continuous publicity to the early treatment of cancer through lectures, films, leaflets, radio talks and traveling museums. 4 Industrial plants and factories working with materials known as capable of producing cancer are to be periodically examined by cancer experts. Professor Manninger finished with the statement that the Hungarian government made huge sacrifices to further a campaign against tuberculosis with the result that it has ceased to devastate the population. Cancer mortality approaches the tuberculosis mortality, so that there is cause for the state to make a substantial sacrifice also in this field.

The Treatment of Venereal Patients in Hungary

The treatment of venereal patients is done in Hungary partly in special dispensaries and partly through the general nursing service and the protection of mothers and infants. Cities are provided with special dispensaries, and the villages are allied with the institutions. The latter work is not yet completed. Dispensaries for venereal patients are organized in cooperation with cities, municipalities and the social insurance. Drugs are free. The dispensaries have modern equipment and are provided with specialists and nurses, and are supervised by the ministry of the interior. The ministry contributes to the maintenance and to the establishment of dispensaries. The organization of new dispensaries is done by a committee consisting of representatives of the ministry of the interior, the social insurance institute and the ministerial commissioner for the prevention of venereal diseases. At present there are fifteen dispensaries in the country and there will be twenty by the end of the year. The number in attendances at the dispensaries amounts to 200,000 a year. The dispensaries are entrusted also with the periodic examination of prostitutes.

The Future of Medical Practice

In his presidential address before the Section of Medical Science and National Health at the last meeting of the Australian and New Zealand Association for the Advancement of Science, held in Melbourne, Dr. J. V. Duhig pointed out in no uncertain terms the weak points in the medicopolitical armor in Australia today. Medicine lays tribute on all the sciences for the promotion of human welfare and the study of human biology in all its manifestations—the structure, development, function and behavior of the body from its primordial conception to maturity and death. The maintenance of health involves a wide view of the human environment, and this view of the functions of medicine necessarily includes a knowledge of man's mental processes and the springs of his behavior. A government which is content to reflect public opinion results in a low state of social culture, and a high one requires a highly advanced, expert, well ordered intelligence ready to lead and to submit to rational restraints and disciplines. In Australia today the tendency of the central government is toward fascism, while in some of the states a thinly veiled communism is enforced. These antidemocratic tendencies are theoretically the trend of the elected representation but in actual fact are the evolved function of the vast bureaucracy of government servants. If science were fully in control of affairs there would be at least a foundation of knowledge and training, a systematic plan and way of approach to an attack on human problems, and above all a spirit of self criticism, moral integrity and the peculiarly refined feeling for truth and accuracy inseparable from good science.

Medicine in the past has failed to have any but a temporary, feeble effect on political theory and practice. Statesmen have seen political possibilities in some features of medical work and used them irrespective of their immediate effect on public development, to bribe the electorate into tranquility now and good will at a future election. The insurance act in Great Britain was of this kind and was typical of Lloyd George's methods—it degraded both people and doctor and completely checked the sound evolution of medicine and social science. This casual empiricism based on a narrow, partial view of the functions of the greatest profession cannot be checked, however, until medicine can control its own destiny, and this control obviously cannot be acquired by mere scientific output but by control of the distribution of its benefits and general application, that is, medicine must eventually include, as must

science generally, training in political methods. By lack of political sense, and for other reasons, medicine has not yet made its full contribution to sociology. The traditional reticence of the profession was manipulated to hide the process of transfer of responsibility from doctor to bureaucrat. What above all the public wants, and should be told, is a statement of medical policy—what doctors are up to and what they are after. Only very childish people are completely satisfied to be told constantly that their doctors are concerned with human welfare and that all is for the best, and to be told nothing more. That sort of empty patronizing paternalism is only exasperating. Nationalization of medicine in the sense understood and practiced in Russia and partially practiced in England will eventually be disastrous—in comparison, that is, with what might be secured.

THE FUTURE OF MEDICAL PRACTICE

Duhig cannot see that any plan of medical service can give the fullest results that leaves out of account the value of private practice, which promotes the growth of a confidential relationship based on mutual trust and sound human interest. The first duty of the doctor is not to treat disease but to cure sick people and to prevent them from falling ill, and the prime requisites in this relationship are care and courtesy on the part of the doctor, and frankness and trust on the patient's part. A relationship of this kind of long standing and extending to all the units of a given family gains enormously in effectiveness, since the doctor works with precision on a very familiar background. No system possible can replace this one of sympathy, trust and understanding. Wherever nationalization has been tried it has failed in two ways—deterioration of the quality of the state-employed doctor, and tendency to development of a purely mechanical relationship. The evils of such a system are obvious. There are more subtle dangers. They are the encroachments made by slow pressure of a fairly enlightened public opinion acting on a profession so preoccupied with immediate tasks that it has been blind to the drift of things. Free or state subsidized services, such as school inspection, maternal and child welfare, dental treatment, diphtheria immunization, vaccination, psychoanalysis, nutrition and regulation of fertility, could and should be part of a private practitioner service but since the profession was unwilling or unable to provide it as part of their system, they can only blame themselves for allowing it to go out of their hands into the control of interested nonmedical sociologists. If this kind of drift becomes general, nationalization will develop automatically, and there are medical men today who find it so hard to maintain the high social standards expected from self-respecting doctors that they would welcome the prospect of a steady, though reduced income from the state. This would end in deterioration. The remedy would be to restore the doctor to a greatly expanded function. The most serious rival to the private doctor is the large public hospital, to some extent greatly overgrown beyond the real demand for such service. A million pounds in bricks, brass and white enamel is a marvelous advertisement for a vote hunter. Half the money now spent in this way might successfully be devoted to an inquiry as to why and how people get sick. The vast propaganda devoted to hospitals encourages the use of them and a slackness of self discipline of the kind that would encourage people to look after themselves and cultivate habits that will avoid illness. There occur many leaks of human beings away from health in a congenial gainful occupation into the indolence and spurious invalidism of a hospital bed or a chronic seat in an outpatient department. A cynical humorist might have some excuse for making hospitals so unattractive that people would want to keep out of them.

The anachronism of honorary medical service to hospitals helps to keep the hospital population high. Charity should

be unnecessary, it presupposes the existence of miserable people who should not exist at all as such.

People must know, though they try to forget that sickness and accident are just as inevitable as death and hunger, thirst, and should be provided for. The fact that medical service was provided free in feudal times to serfs is no argument for doing the same for free men in a democracy. The form of insurance that ought to be envisaged is precisely that which prudent men use today. The sort of insurance favored by Dr Duhig is that which places the insured in possession of money to pay his accounts when he needs it. The plan eventually worth considering is that of free choice of doctor by patient, and payment directly by the patient to the doctor, either out of savings or as a draft on a policy against sickness.

Early Diagnosis of Tuberculosis

The Federazione per la lotta contro la tubercolosi met recently in Palermo, under the chairmanship of Dr Gruber. The topic discussed was the early diagnosis of tuberculosis. Dr Bompiani spoke on tuberculosis of the female genital organs, the diagnosis of which in childhood is rather presumptive. Tuberculous ascites and tuberculosis with impaired intestinal functions are the two forms most frequently found at early ages. The diagnosis of peritoneal localization of the disease is usually made. At puberty, delay in the appearance of menstruation and the presence of oligomenorrhea or dysmenorrhea are frequent. In some cases amenorrhea persists through youth and maturity and there are functional disturbances, pain in the lower part of the abdomen and sterility. Calandra spoke on the early diagnosis of tuberculosis of the neck of the femur, giving the anatomic reasons that account for the frequency of this form of tuberculosis in children from 2 to 10 years of age and for the rare occurrence of the disease in adults. Tuberculosis of the femoral neck may be located at any of the different zones of the neck and may be a form either asymptomatic or painful. The disease frequently extends to the hip joint. The speaker detailed the technique of his surgical treatment, which is based on the perforation of the bone at the tuberculous focus. Pavone spoke on the diagnosis of renal tuberculosis. The speaker regards cystoscopy, meatoscopy and especially the functional test of the kidney of more diagnostic value than the other methods.

Society Reunion

The Latin Section of the Società di Gastroenterologia di Rome met recently at that city under the chairmanship of Cesare Frugoni, professor of clinical medicine. Dr Muro spoke on intestinal trichomoniasis. He said that *Trichomonas hominis* may be found in the stomach of man as well as in the rectum and colon and that in certain cases it is pathogenic. The frequent clinical picture is that of chronic enterocolitis, the main symptom of which is the irregularity of intestinal evacuation. In order to detect the parasite in the feces it is advised to examine the feces immediately after evacuation. If there are a few parasites fecal cultures can be prepared for examination. According to the speaker the treatment of the infection consists in the administration of enemas prepared with chinofon and the administration of vioform by mouth.

Institution for Correction of Facial Deformities

An institution for the correction of facial deformities, congenital or traumatic from war or industrial accidents, recently opened in Milan. There are now thirty beds, forty more beds are in preparation. Persons with facial deformities from war are given the preference over other applicants for admission.

Marriages

HENRY FRANKLIN DE WOLF, Little Rock, Ark., to Miss Helen Lawton Clarke in Estill, S C, recently

ROBERT COOPER BYRNE, Hatfield, Mass., to Miss Ethel Irene Redman of Franklin, N H, August 1

MICHAEL J O'CONNOR, Spokane, Wash., to Miss Chonita Bovet of San Mateo, Calif, June 6

BENJAMIN JOSEPH ROSENTHAL to DR. ELIZABETH WILEN, both of Brooklyn, August 9

WILLIAM M DAVIDSON, Seattle, to Miss Harriet Shipman of Montclair, N J, June 27

THOMAS P FOLTZ, to Miss Eleanor Stuart Albers, both of Fort Smith, Ark, July 15

E ALEXANDER SCOTT, St James, Mo., to Miss Nancy Elaine Honea of Rolla, June 14

DAVID E ENGLE, Martinsville, Ind., to Miss Faith Ritz of Royal Center, June 8

ROSS E MAYNARD to Miss Marjorie Lovejoy, both of Pine Bluff, Ark, June 16

HAROLD SHELLOW to Miss Vivian Inez Van Ronkel, both of Chicago, July 8

Deaths

John Tilden Burrus ☉ High Point, N C, North Carolina Medical College, Davidson, 1898, Chattanooga (Tenn.) Medical College, 1903, past president of the North Carolina State Board of Health and the Medical Society of the State of North Carolina, formerly visiting lecturer in clinical surgery, Duke University School of Medicine, Durham, fellow of the American College of Surgeons, served during the World War, at one time member of the state legislature, chief of staff and head of the department of surgery, Randolph Hospital, Asheboro surgeon to the Davidson Hospital, Lexington, Thomasville (N C) Baptist Orphanage and the North Carolina Public Service Company, chief surgeon to the High Point, Thomasville and Denton Railroad, consulting surgeon to the Southern Railway, formerly member of the governing board of the state hospital for the insane, Morganton, aged 58, owner of the Burrus Clinic and chief of staff of a hospital bearing his name, where he died, June 8, of coronary thrombosis and hypertension

Sidney Kohn Simon ☉ New Orleans, Tulane University of Louisiana Medical Department, New Orleans 1903, specialist in internal medicine with special attention to gastroenterology, in 1922 a member of the House of Delegates of the American Medical Association, and from 1922 to 1924 secretary of the Section on Gastro-Enterology and Proctology, and chairman from 1925 to 1926 assistant professor of clinical medicine at his alma mater and professor of gastro-enterology at the Tulane University Graduate School of Medicine, past president of the American Society of Tropical Medicine, member of the American Gastro-Enterological Association, fellow of the American College of Physicians, chief of the department of gastro-enterology, Touro Infirmary aged 58, died, August 5

Herman Bennett Slotkin ☉ Philadelphia Jefferson Medical College of Philadelphia, 1925, member of the American Academy of Ophthalmology and Oto Laryngology, instructor in neurology at the University of Pennsylvania Graduate School of Medicine, assistant neuro-otologist at the Graduate Hospital of the University of Pennsylvania, served in the Medical Corps chemical warfare division, during the World War, assistant otolaryngologist to the Jewish Hospital aged 37 died August 1 in the Manhattan General Hospital, New York, following a thoracoplasty

Clarence Anderson Patten ☉ Philadelphia Jefferson Medical College of Philadelphia 1916 professor of neurology and vice dean for neurology and psychiatry at the University of Pennsylvania Graduate School of Medicine, member of the American Neurological Association American Psychiatric Association and the Association for Research in Nervous and Mental Disease, served during the World War, neurologist to the Philadelphia General, Lankenau and Orthopedic hospitals, associate editor of *Cyclopedia of Medicine* aged 46, died June 2

Herbert de Grove Sherman, White Plains N Y New York Homeopathic Medical College and Flower Hospital 1915 member of the Connecticut State Medical Society and the

Associated Anesthetists of the United States and Canada, served during the World War, roentgenologist to the Greenwich (Conn) Hospital, aged 46, died, June 18, in the Grasslands Hospital, Valhalla, of subacute bacterial endocarditis and bronchopneumonia

Edward Gilmer Thompson ☉ Memphis, Tenn., University of Pennsylvania School of Medicine Philadelphia, 1911, associate professor of medicine, University of Tennessee College of Medicine, served during the World War, fellow of the American College of Physicians, member of the staffs of the Methodist and John Gaston Memorial hospitals, and the Illinois Central Railway System, aged 51, died, June 21, of acute myocardial insufficiency

Alquin Jay Davis ☉ Farmingdale, N Y, University of Pennsylvania School of Medicine, Philadelphia, 1909, president of the New York State Association of Sanatorium Superintendents and Boards of Managers on the consulting staffs of the Nassau Hospital, Mineola and the Meadowbrook Hospital, Hempstead aged 48, superintendent of the Nassau County Sanatorium, where he died, June 18, of pneumonia

Charles Louis Upton ☉ Greenfield, Mass., University of Pennsylvania Department of Medicine, Philadelphia, 1896 served during the World War, at one time member of the school committee of Shelburne Falls, on the staffs of the Farren Memorial Hospital Montague City, the Franklin County Public Hospital and the Greenfield Isolation Hospital, aged 65, died May 25, of chronic nephritis and myocarditis

Evan Styles Potter, New York University of the City of New York Medical Department 1891, formerly medical expert to the law department of the city and medical examiner to the Civil Service Commission, on the staffs of the Columbus Hospital and the West Side Hospital, aged 66, died, May 26, in the New York Post-Graduate Medical School and Hospital

Jacob Frank ☉ Chicago, University of Buffalo School of Medicine, 1882 past president of the Chicago Medical Society and the Chicago Surgical Society, retired colonel, Illinois National Guard, served during the World War, consulting surgeon to the Grant and Columbus hospitals, formerly surgeon to St. Elizabeths Hospital, aged 80, died, August 11

Walter Monroe Matthews Jr, Little Rock, Ark University of Arkansas School of Medicine, 1915, member of the Arkansas Medical Society, chief medical officer for the Little Rock regional office of the Veterans Administration, served during the World War, aged 47, died, May 2, in the Fitzsimons General Hospital, Denver, of tuberculosis

Earl Henry Lormor ☉ Buffalo, University of Buffalo School of Medicine, 1914, served during the World War, aged 47, served in various capacities on the staffs of the City Hospital, Buffalo State Hospital, Millard Fillmore Hospital and the Buffalo General Hospital, where he died, May 25, of ruptured diverticulitis of the sigmoid

James Finley Bell, Englewood N J University of the City of New York Medical Department, 1883, member of the Medical Society of New Jersey, past president of the Bergen County Medical Society, on the staff of the Englewood Hospital, aged 76, died, June 16, of cardiovascular disease

Frank Eugene Haskins ☉ Boston, Tufts College Medical School, Boston, 1903, professor of pharmacology at his alma mater and formerly secretary of Tufts Medical College and Dental School, member of the Associated Anesthetists of the United States and Canada aged 61 died, May 24

John L Kirkpatrick, Los Angeles, University of Southern California College of Medicine, Los Angeles, 1899, member of the California Medical Association, on the staff of the Queen of Angels Hospital and the Los Angeles General Hospital aged 61, died, May 17, of carcinoma of the liver

Michael Angelo Bailey, Hartford Conn, College of Physicians and Surgeons Baltimore, 1893 member of the Connecticut State Medical Society formerly member of the board of education, was connected with St. Francis Hospital in various capacities, aged 77, died, June 6

Helen Cooley Palmer, San Marino, Calif, New York Medical College and Hospital for Women 1895, at one time professor of ophthalmology and associate professor of gynecology at her alma mater, aged 77, died May 19, of cardiac rupture and coronary sclerosis

John A Roth, Red Hill, Pa, University of Pennsylvania Department of Medicine Philadelphia, 1876 member of the Medical Society of the State of Pennsylvania for many years a member of the board of education, aged 82, died, May 19, of carcinoma of the stomach.

Arthur Charles Dana, Fond du Lac, Wis., Milwaukee Medical College, 1911, served during the World War, formerly city physician and health officer, aged 49, on the associate staff of St. Agnes Hospital, where he died, May 25, of cholecystitis and chronic myocarditis.

James Sherman Mosher, Williamsport, Pa., College of Physicians and Surgeons, Baltimore 1891, member of the Medical Society of the State of Pennsylvania, served during the World War, aged 69, died, May 10, in Pittsburgh of cerebral hemorrhage.

Ward Lafayette King, Muncy, Pa., College of Physicians and Surgeons, Baltimore, 1880, member of the Medical Society of the State of Pennsylvania, aged 80, on the staff of the Muncy Valley Hospital, where he died, May 24, of chronic myocarditis.

Ezra Clark Chase, Plymouth, N. H., Eclectic Medical College of Maine, Lewiston, Maine, 1884, member of the New Hampshire Medical Society, on the staff of the Emily Balch and Soldiers and Sailors Memorial Hospital, aged 78, died, May 25.

Franklin K. Martin, Havana, Ill., Eclectic Medical Institute, Cincinnati 1882, member of the Illinois State Medical Society, aged 74, died, May 17, in the Methodist Hospital, Peoria, of carcinoma of the gallbladder and liver.

James Lewis Lee, Pinehurst, Ga., University of Georgia Medical Department, Augusta, 1899, served during the World War, aged 57, died, May 16, in the Veterans Administration Facility, Atlanta, of cardiorenal vascular disease.

Charles Edward Webb, Natchitoches, La., Tulane University of Louisiana School of Medicine, New Orleans 1930, on the staff of the Natchitoches Hospital, aged 38, died, May 24, in Jennings, of carcinoma of the stomach.

Emerson Augustus Ludden, North Brookfield, Mass., Albany (N. Y.) Medical College, 1888, member of the Massachusetts Medical Society, for many years local health officer and school physician, aged 74, died May 31.

William Chenitz, Newark, N. J., University of Maryland School of Medicine, Baltimore, 1930, member of the Medical Society of New Jersey, aged 32, died, May 17, in the Beth Israel Hospital, of carcinoma of the stomach.

Edward Emery Baumeister, San Francisco, University of California Medical Department, San Francisco, 1904, member of the California Medical Association, fellow of the American College of Surgeons, aged 59, died, May 4.

Alfred Joseph Jackson, Hempstead, N. Y., Howard University College of Medicine, Washington, D. C. 1927, member of the Medical Society of the State of New York, aged 37, died, May 12, of rheumatic heart disease.

Howard Lansing Waldo, Flushing, N. Y., Regents of University of State of New York, 1875, member of the Medical Society of the State of New York, aged 83, died, May 7, of arteriosclerosis and chronic endocarditis.

Stanislas Martel, Boston, School of Medicine and Surgery of Montreal, Que., Canada 1893, member of the Massachusetts Medical Society, on the staff of the Lynn (Mass.) Hospital, aged 65, died, May 16, of pneumonia.

John W. Good, Fordland, Mo., St. Louis College of Physicians and Surgeons, 1897, member of the Missouri State Medical Association, county coroner, local registrar of vital statistics, aged 75, died, May 11.

William E. Royster, Chanute, Kan., Louisville (Ky.) Medical College 1907, member of the Kansas Medical Society, on the staff of the Johnson Hospital, aged 66, died, May 31, of a self-inflicted bullet wound.

Henry B. Golden, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1896, aged 62, died May 20, in the Philadelphia General Hospital, of myocarditis and benign prostatic hypertrophy.

Arthur P. Hunnemann, Chicago, Harvey Medical College, Chicago 1903, formerly on the staff of the Illinois Eye and Ear Infirmary, aged 66, died May 20, of carcinoma of the bladder with metastases.

Frederick Jesse Weld, Rockford, Ill., Rush Medical College, Chicago 1884, member of the Illinois State Medical Society, aged 76, died May 24, in St. Anthony's Hospital, of cerebral hemorrhage.

Joel Grosner, Jersey City, N. J., Cornell University Medical College, New York 1899, aged 58, died, May 23, in the Veterans Administration Facility, Lyons, of chronic myocarditis and arteriosclerosis.

James Martin, Magnolia, Del., Medico-Chirurgical College of Philadelphia, 1893, member of the Medical Society of Delaware, past president of the Kent County Medical Society, aged 69, died, May 24.

William Patrick Kenealy, Washington, D. C., Georgetown University School of Medicine, Washington, 1911, also a druggist, aged 63, died, May 25, in the Sibley Hospital, of brain tumor.

James Harvey Ferguson, Kempton Ind., Medical College of Indiana, Indianapolis, 1902, aged 66, died, May 12, in St. Vincent's Hospital, Indianapolis, of angina pectoris and coronary embolism.

Wilber T. Kennedy, Johnson City, Tenn., Tennessee Medical College, 1905, member of the Tennessee State Medical Association, aged 57, died, April 7, of carcinoma of the prostate.

Harry Bell Nunnally, Monroe, Ga., Atlanta College of Physicians and Surgeons, 1906, on the staff of the Walton County Hospital, aged 53, died, May 13, of cardiac asthma.

Charles L. La Barge, St. Louis, St. Louis Medical College, 1874, for many years diagnostician for the city health department, aged 85, died, May 9, of angina pectoris.

John Ferguson Hope, Drexel Hill, Pa., Jefferson Medical College of Philadelphia, 1904, aged 53, died, May 21, in the Delaware County Hospital, of coronary occlusion.

Bessie James Garver, Los Angeles, State University of Iowa College of Medicine, Iowa City, 1890, aged 82, died May 10, of hypostatic pneumonia and senile dementia.

Raymond Nathaniel Jackson, Brunswick, Ga., Meharry Medical College, Nashville, Tenn., 1905, aged 52, died, May 11, of myocarditis and interstitial nephritis.

Walter Witmore Senn, Williamsport, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1907, aged 55, died suddenly, May 15, acute nephritis.

Malcolm J. Mooney, Quebec, Que., Canada, McGill University Faculty of Medicine, Montreal, 1898, aged 63, died, May 25, in Tokyo, Japan, of pneumonia.

Claude Nicholson Lacey, Demopolis, Ala., University of Alabama Medical Department, Mobile, 1900, aged 57, died, May 17, of a self-inflicted bullet wound.

John Mackenzie & Reese, Mich., Detroit College of Medicine, 1893, aged 73, died, May 19, in St. Mary's Hospital, Sarnaw, of cerebral hemorrhage.

Marshall Dwight Jennings, St. Louis, St. Louis College of Physicians and Surgeons, 1888, aged 75, died, May 18, of carcinoma of the rectum.

Albert Henry Daniel Heppner, Los Angeles, Long Island College Hospital, Brooklyn, 1897, aged 73, died, May 10, of cirrhosis of the liver.

Henry M. Ammond, West Branch, Mich., Jefferson Medical College of Philadelphia, 1882, aged 81, died, May 30, of cerebral hemorrhage.

Orris E. Lett, Montgomery, Ind., Kentucky School of Medicine, Louisville, 1901, formerly county coroner, aged 61, died April 12.

William A. Longanecker, Los Angeles, Jefferson Medical College of Philadelphia, 1876, aged 87, died, April 3, of chronic myocarditis.

Frank Ward Lynch, El Paso, Texas, Medico-Chirurgical College of Philadelphia, 1910, aged 57, died April 1, of cerebral hemorrhage.

Herbert D. Jenckes, Pipestone, Minn., College of Physicians and Surgeons of Chicago, 1884, aged 82, died in May of carcinoma.

Frank Jacob Sofge, Cincinnati, Medical College of Ohio, Cincinnati, 1904, also a pharmacist, aged 67, died suddenly April 21.

Hugh Angus McColl, Milton, Ont., Canada, University of Toronto Faculty of Medicine, 1889, died, May 14, of heart disease.

Joseph L. Mackey, Charleston, Tenn., Hospital College of Medicine, Louisville, Ky., 1890, aged 75, died April 5.

Henry H. Gambill, Blaine, Ky., Atlanta Medical College, 1895, formerly bank president, aged 62, died May 9.

Charles A. Strasburg, Cridersville, Ohio, Pulte Medical College, Cincinnati 1903, aged 74, died in April.

Alfred Edwards, St. Louis, Dallas Medical College, Texas 1904, aged 78, died May 7, in Reno, Nev.

Oscar A. Hubbs, Butler, Ohio, Pulte Medical College, Cincinnati 1879, aged 85, died May 1.

PARANA MATÉ AND PYLAIDES A South American Tea and a "Pile Cure" Declared Fraudulent

"Parana Mate" was the proprietary name employed by the Rundle-Murphy Company of Westport, Conn., for one of the innumerable brands of verba mate, or Paraguay tea, that have flooded the North American market during the last several years.

Parana Mate was exploited as an invigorating beverage of amazing medicinal value for nervous ailments, convalescents, anemics, and of especial value for tired business men and women.

A romantic historical background was skilfully woven into the advertising of Parana Mate. The tea was alleged to have been discovered several hundred years ago by missionaries to South America. The Spanish grandees, it was said, were 'not slow in becoming acquainted with the almost miraculous powers of the infusion drunk by the Indians.

Mate does not directly affect the nerve system as do coffee and tea, but rather localizes its action in the muscular system and Vital Organs." Yet, paradoxically, it was also claimed to "Regenerate lost Nerve Force! Build up strong, sound nerves through natural methods." The unique process by which mate built up strong nerves without affecting them was left to the imagination.

Among the other amazing accomplishments claimed for Parana Maté was its ability to prevent hunger, which, according to the exploiters, made the tea eligible for combating obesity.

According to the directions, Parana Mate was to be brewed into a tea, one "heaping teaspoonful of Maté for each cup wanted and one extra for the pot." The drinking of "four or five cups a day" was advocated by the promoters.

The government's chemical analysis of Parana Maté, "the Fountain of Youth," showed that the only active ingredient was caffeine, of between $\frac{3}{4}$ and $\frac{3}{4}$ grain per cup which is slightly less than that contained in a cup of tea or coffee. "In addition, small quantities of chlorophyll and tannin were also present in insignificant amounts."

The Post Office authorities held that Parana Mate had no more healing properties than tea or coffee, that the drinking of four or five cups daily as directed might be harmful in the case of children and aged persons, and that the beverage would not afford "relief from tropical fevers and other body, as well as mental ailments." The report further stated that inasmuch as Parana Maté had no value as a food, it would not "prevent hunger" and accordingly would be of no assistance in combating obesity.

In addition, the concern sold through the mails a product, "Pylades," for the cure of hemorrhoids. The exploiters advertised it as a 'soluble suppository,' claiming that 'this formula was prepared by one of America's foremost specialists,' going on to name a former professor of the New York Post Graduate School, who, the records show died as long ago as 1917. The government chemists reported that Pylades consisted essentially of ichthyol, cannabis Americana and the alkaloid hydrastin, in a base of cacao butter. The report pointed out the danger in the absorption of cannabis Americana in the system and the likelihood of its forming 'a pernicious habit causing great injury to the user' although the promoters of Pylades represented the mixture as a safe treatment. The report showed further, that this nostrum would have no remedial effect whatever in the treatment of hemorrhoids.

According to the government report, the promoters were cited in August 1934 to show cause why a fraud order should not be issued against the names then used in the conduct of the enterprise. The concern at that time 'agreed to discontinue the scheme and never to resume it.' However, the resumption of the enterprise brought about the recommendation of Post Office Solicitor Karl A. Crowley that a fraud order be issued against the Rundle-Murphy Company, Importers, the Rundle-Murphy Company, and their officers and agents. On evidence satisfactory to him, the Postmaster General on June 9, 1936 closed the United States mails to the concern and parties above mentioned.

Correspondence

LONG'S CONTRIBUTION TO DISCOVERY OF ETHER

To the Editor—In different papers concerning the discovery of ether anesthesia by Crawford W. Long it has been stated that one of the reasons Long was seeking an anesthetic was to relieve women of the pains of childbirth.

Some time ago Dr. Joseph B. De Lee wrote me asking if I knew the date of Dr. Long's first administration of ether in childbirth. For the past several months I have been investigating this matter with some of the members of Dr. Long's family, and I now find out that on Dec. 27, 1845, Dr. Long used ether in delivering his own second child, born at Jefferson, Ga. This date is attested by the family Bible record now in possession of Mrs. Eugenia Long Harper, Gay, Ga., sole surviving child of Crawford Long. Mrs. Harper tells me that the family often heard their mother say that Dr. Long administered ether to her when this child was born.

We read in the Encyclopedia Britannica that Sir James Y. Simpson used ether in obstetrics in 1846 and was the first to use chloroform in 1847. If these dates are correct, Crawford Long not only used ether anesthesia in the first surgical operation (March 30, 1842) but also was the first to use an anesthetic in obstetrics, Dec. 27, 1845.

HEMOLYTIC SHOCK FOLLOWING BLOOD TRANSFUSION

To the Editor—The subject of hemolytic shock following blood transfusion is again arousing interest, owing partly to the publication of studies by Professor Hesse and his associates in Leningrad, whose work was reviewed editorially in THE JOURNAL, June 27.

The clinical syndrome accompanying and following hemolysis in vivo in man is fairly well known. During or soon after transfusion the recipient becomes acutely ill with severe pains in the lumbar region, dyspnea and cyanosis, chills, fever and collapse. The blood serum contains free hemoglobin and the van den Bergh test gives an atypical biphasic reaction within two hours. If hemolysis is extensive, hemoglobin appears in the urine. Jaundice may be noted as early as eight hours after the transfusion. The acute phase of the reaction lasts only a couple of hours. Then the patient may recover promptly or signs of grave renal insufficiency may appear. In the latter case, anuria or oliguria quickly supervenes. The patient vomits frequently. There is progressive nitrogen retention and death in coma follows about ten days after the transfusion. Pathologic examination of the kidneys reveals necrosis of the tubular epithelium, interstitial polymorphonuclear infiltration, and masses of pigment derived from hemoglobin in the tubular lumens. The glomeruli appear normal. The picture is almost the same as, if not identical with, that seen in blackwater fever and in quinque hemolysis.

The most important phase of this problem is the effect of hemoglobinemia and hemoglobinuria on the kidney, which the Russian group ascribes primarily to the ischemia of the kidneys as the result of the vasoconstrictor action of hemoglobin. They advocate the transfusion of compatible blood or blood serum to treat the anuria. A critical analysis of their experimental work seems indicated.

Mason and Mann (*Am J Physiol* 98:181-185 [Sept] 1931) obtained only transient vasoconstriction in the kidney of the dog and the frog after the intravenous injection of hemoglobin. In one dog 75 cc. of laked blood per kilogram produced only

temporary reduction in renal volume. Permanent anuria has been produced in man with smaller quantities of incompatible blood.

My colleagues and I have reproduced in dogs quite accurately the picture of renal insufficiency by the injection of hemolyzed blood into dogs with acid urines (THE JOURNAL, February 1, p 416). The dogs develop oliguria or anuria and die in coma from the third to the tenth day after transfusion, with blood urea nitrogen values of from 119 to 350 mg per hundred cubic centimeters. The kidneys show the typical nephropathy. This picture cannot be produced in dogs with alkaline urines.

The Russian workers have published similar experiments except that the reaction of the urine was not noted (Iljin *Arch f klin Chir* 181 240-249, 1934). Their dogs died within two days following transfusion, and the highest blood nonprotein nitrogen value obtained was 89 mg per hundred cubic centimeters. No pathologic studies were reported. It is evident that this is not an accurate reproduction of the clinical syndrome of renal insufficiency following hemolysis.

The relation between urinary acidity and renal insufficiency from hemoglobinuria has been established by Yorke and Nauss (*Am Trop Med & Parasitol* 5 287 1911-1912) and Baker and Dodds (*Brit J Exper Path* 6 247, 1925) in the rabbit and by us in the dog. A complete physiologic explanation of the effect of hemoglobin on the kidney ought to account for these facts.

ELMER L. DEGOWIN, M.D., Iowa City

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

TESTS FOR UREA AND RENAL FUNCTION

To the Editor—Please describe the urea clearance test the Van Slyke and Cope technic, also its clinical value and state normal and pathologic percentages also kindly publish the method for carrying out the concentration test for renal function the technic as described by Lashmet and Newburgh also the urea ratio test as employed by Moseenthal stating the range of the normal ratio. Please omit name. M.D. Minnesota

ANSWER—The blood urea clearance test is a test of renal efficiency based on the cubic centimeters of blood cleared of urea by the kidneys per minute.

The technic is usually the following:

- 1 At 8 a.m., breakfast without coffee or tea.
- 2 At 9 a.m., empty the bladder and discard the specimen. Give 100 cc of water to drink.
- 3 At 9:50 a.m., obtain 5 cc. of venous blood for urea estimation.
- 4 At 10 a.m. collect a total specimen of urine. Give 100 cc of water to drink.
- 5 At 11 a.m. collect another total specimen of urine.

Estimate the blood urea in milligrams of urea per hundred cubic centimeters. Measure the amount of each hourly specimen of urine. Calculate the volume excreted per minute for each hour period. Estimate the urine urea in milligrams per hundred cubic centimeters in each. If more than 2 cc is excreted per minute determine the maximum clearance (C_m). If less than 2 cc is excreted per minute estimate the standard clearance (C_s).

The percentage of average normal is $C_m = \frac{133 \times U \times I}{B}$

$$C_s = \frac{133 \times U \times I}{B}$$

C_m is the maximum clearance. C_s the standard clearance. U = milligrams of urea in 100 cc of urine. B = milligrams of urea in 100 cc of blood and I = the volume of urine excreted per minute.

The results are expressed in percentage of the average normal and less than 75 per cent may be considered pathologic. Early acute nephritis may show a normal urea clearance. In most

cases it falls to 50 per cent of normal within the first 6 months. For a good prognosis the urea clearance figure returns to normal in four months. In arteriosclerosis of the disease the urea clearance is usually normal until the terminal state, when it drops with the development of uremia. The blood urea nitrogen does not show an increase until the urea clearance diminishes to about 50 per cent of normal. The prognosis is bad when the urea clearance reaches 20 per cent of normal. Uremic symptoms are present with values less than 5 per cent, and death occurs within a few days.

The test is a procedure requiring extensive and careful examinations and is thus comparatively expensive. When carried out it reveals kidney function with a high degree of accuracy. For practical purposes a carefully conducted urine concentration test, a blood urea determination and examination of the sediment are as sensitive an index of early renal damage as the urea clearance test.

Van Slyke and Cope (*Proc Soc Exper Biol & Med* 29 1169 [May] 1932) have described a simplified colorimetric method for determination of the blood urea clearance.

The urea contents of urine and blood are compared in a colorimeter in such a manner that a single reading gives directly the percentage of average normal renal function in terms of the blood urea clearance. The urine is first diluted to such an extent that, if the clearance, either standard or maximum, is the average for a normal subject, the urea concentrations of blood and dilute urine will be equal. The urea in both blood and urine is converted into ammonia with urease, proteins and other interfering substances are removed, and the ammonia contents of the two filtrates are compared colorimetrically.

No standard solutions are required, because the blood is compared directly with the urine. The technic, with the necessary reagents, treatment of urine and blood, nesslerization and comparison of blood and urine filtrates, and the calculation will be found in the reference mentioned. The details are too lengthy to be given here.

The disproportionate elevation of the blood urea nitrogen may be resorted to as a test for renal function. Moseenthal and Hiller (*The Relation of the Nonprotein Nitrogen to the Urea Nitrogen of the Blood* (*J Urol* 1 75 [Feb] 1917) found that while the percentage of the urea nitrogen of the total nonprotein nitrogen in the blood in the presence of normal renal function is between 40 and 50 per cent, when kidney activity is reduced this rises to 80 or even 90 per cent. This holds true as an index of renal function whether the blood urea nitrogen is high or is reduced by diet. On the other hand when the urea nitrogen of the blood drops because there is improvement of renal function, the percentage of the urea nitrogen of the total nonprotein nitrogen again assumes a normal level.

The urine concentration test is a test of the kidney's power to concentrate waste products removed from the blood. There is no serious renal impairment if the specific gravity of the urine can be elevated to 1.025 or over. If an ordinary specimen shows a specific gravity of 1.025 or higher, no further examination except for sugar and microscopic sediment need be done.

Lashmet and Newburgh described their method of performing the concentration test in THE JOURNAL, Oct 22, 1932 p 1. The technic is as follows:

About 6 p.m. eat the usual supper, avoiding fluids of any kind such as coffee, tea, milk or soup. Empty the bladder and discard the specimen. On waking in the morning empty the bladder and save the urine in bottle 1. An hour later collect specimen 2 and two hours after this one collect specimen 3.

Take the specific gravity carefully of each specimen. Use only a high-grade urinometer. Examine the sediment carefully for casts, red blood cells or pus. If the specific gravity is 1.025 or less give a dry diet for one day, examining the specimen passed on the following morning.

The dry diet should consist of:

| | | |
|-----------|------------------------------|------------------------|
| Breakfast | Cornflakes 1/2 cup | bread (toast) 2 slices |
| | butter 2 squares | rich cream 1/4 cup |
| | 1 tablespoonful | |
| Lunch | Beefsteak 4 by 4 by 1/2 inch | one baked potato |
| | crackers 4 | butter 2 squares |
| Dinner | Baked potato 1 | lettuce, 1/2 head |
| | butter 2 squares | dates 4 |
| | no juice 1/2 | |

In addition to foregoing 1 gm of salt per

Collect the urine from 8 p.m. until 8 a.m. the following morning on which no breakfast is taken. Get a specimen at 10 a.m. and a third at 12 noon.

With this test normal kidneys are able to excrete a urine to a specific gravity of 1.029 to 1.032. A patient with essential hypertension will show 1.025 to 1.029.

nephritis, the maximum concentration decreases to as low as 1010, the low figure occurring in the severe types. The maximum is usually 1020 or less before the phenolsulfonphthalein is diminished. With heart failure the level is around 1020.

SYMPTOMS POSSIBLY ASSOCIATED WITH ARSENICAL POISONING

To the Editor—A white man aged 65, single, worked in a store selling wall paper for twenty-nine years. During the last four years he has done nothing. He is of slender type 6 feet 4 inches (193 cm) tall; is fairly well nourished and weighs 160 pounds (73 Kg). He has lost the sensation of taste and smell. He complains of generalized weakness and insomnia; this is not constant but occurs at indefinite intervals. He feels shaky within has no desire for food and has a slimy taste in his mouth with a disagreeable odor. These complaints have been occurring off and on for the last four years. The past history is essentially negative. The family history is negative. He does not indulge to excess in anything. He smokes and chews tobacco occasionally and drinks one or two glasses of whisky perhaps two or three days a week. The family condition is good without financial worries. The patient never married. The skin is normal and has a pasty color. It was always this color. The eyes are normal. The patient wears glasses. There is no obstruction in the nose and no discharge. He is partly edentulous. The remaining teeth have gold crowns. Roentgen examination has shown no devitalized or abscessed teeth. The tongue is slimy with a brownish coating. The saliva is thick. The tonsils are present. The neck is normal. The chest is well developed and symmetrical. Expansion is equal on the two sides and there is no evidence of a pathologic condition. There are no murmurs. The heart has good tone and regular rhythm with a rate of 74 a minute. There is no palpitation. The abdomen is thin; there are no herniations or tenderness. The marginal lines are normal. The genitalia and the rectum are normal. The prostate is atrophied. Normal reflexes are present in the extremities. The patient has marked strength in the hands, arms and legs. He has a strong grip. There is no evidence of muscle atrophy or dystrophy. A gastro-intestinal and gallbladder study was negative. It showed good function. The urine is amber colored. The specific gravity ranges from 1.016 to 1.22. There are no casts or albumin. It is acid in reaction. Repeated Wassermann tests have been negative. The blood sugar is 95 mm. per hundred cubic centimeters. Red blood cells number 3,800,000; hemoglobin 80 per cent (Tallqvist); white blood cells 6,300 with 74 per cent polymorphonuclears, 22 per cent lymphocytes, 1 per cent basophils, 2 per cent nuclears and 1 per cent eosinophils. He has been treated with various of the herbal groups, valerian and chloral with little or no effect. For stomach stimulants he has received gentian, calumba, nux vomica and hydrochloric acid without effect. I would appreciate any information you may be able to give in the treatment of this patient.

J. A. MARCUSO M.D., Meadville, Pa.

ANSWER—At the age of 65 some of the dysfunctions described conceivably might be attributed to physiologic degenerative changes. In any person with twenty-nine years of exposure in selling wallpaper, a suspicion that arsenic poisoning may have existed is tenable. Arsenic poisoning is still arising from colors used in wallpaper printing. Exposure in a single room lately papered, if occupied before complete drying or under other circumstances of providing considerable moisture in the paper, may lead to arsenic poisoning. In this ex-wallpaper salesman, unexposed for the last four years, it is unlikely that active arsenic poisoning persists, so that any theory contemplating a diagnosis of earlier arsenic poisoning must consider present lesions as sequelae and probably uneradicable results from the earlier action of arsenic. It probably would be quite futile to attempt to recover arsenic from the hair of the head at this late time, or from any other tissues of the body. A more profitable line of endeavor may be found in very careful history taking as to obscure diseases of the past (that is, during the twenty-nine years of contact with wallpaper), seeking evidences of acute arsenic poisoning, such as attacks of headache not accounted for otherwise, eruptions and abnormal coloring of the skin, loss of nails and hair, warty growths on the skin, rhinorrhea, gastro intestinal upsets, vomiting, diarrhea, abdominal pain (none accounted for through a plausible explanation) peripheral neuritis, excessive fatigability or muscular weakness. Further, the history inquiry should seek to establish the extent of contact with wallpaper and particularly exposure under conditions in which wallpaper was stored, in cellars or otherwise, where undue moisture was present. Arsenic is capable of bringing about a great variety of obscure lesions. It is not beyond reason to believe that possibly arsenic may have brought about minute fibrosis within the central nervous system to the point of occasioning the loss of the special senses described.

This one suggested lead should not be investigated to the exclusion of all others. A careful examination at the hands of a highly skilled neurologist might disclose entirely different possibilities. Even though it became possible to accept arsenic poisoning as the proximate cause of the present condition, it is unlikely that any treatment may eradicate the insult to the tissues already established. Symptomatic treatment, such as for the gastro intestinal disturbances, is the line of procedure likely to serve the patient's best interests.

TREATMENT OF SYPHILIS

To the Editor—I should appreciate advice on the following problem. A man, aged 25, came to my office May 17, 1935 complaining that the hair on his legs was coming out. He had had no chancre and felt all right. I made a Wassermann test and it was 4 plus. I have given him a total of nine injections of mapharsen, eighteen of neosarsphenamine and thirty-six of a bismuth compound during a thirteen months period according to the modified continuous system of therapy. May 13, 1936, the Wassermann reaction was negative. A spinal tap revealed 10 cells, globulin negative, Wassermann reaction negative. No differential was done. Will you be good enough to advise me as to future treatment?

FREDERICK B. DEVITT M.D. Oneonta, N. Y.

ANSWER—The cell count of 10 lymphocytes in the spinal fluid reaches the upper limit of normal and warrants further consideration even though the blood Wassermann reaction is negative.

It would seem advisable now to start giving the patient some rest periods from treatment. For example, as he has had no treatment since June 17, he should continue with the rest period until August 1 and then have a course of twelve injections of a bismuth compound at the rate of two a week. This should be followed by a rest period of two months and a repetition of the course of twelve injections of the bismuth compound. A blood Wassermann test should be done at this time and, if negative, two similar courses of a bismuth compound are to be given, with a six months rest interval between them. On the other hand, if the blood Wassermann reaction is found to be positive, a spinal fluid examination should again be made, because it has been shown that a relapse of the blood Wassermann reaction in a patient with early syphilis is usually associated with a positive spinal fluid test. Irrespective of whether or not the Wassermann reaction remains negative, the spinal fluid examination must be repeated because of the cell count of 10 lymphocytes before the patient is placed on observation. When these prescribed courses of bismuth preparations are completed and the serologic reaction is negative, the patient is placed on parole or observation. He should be urged to report for a physical examination and a Wassermann test at intervals of six months for the next two years and then once a year for the next three years. If at the end of this time the Wassermann and spinal fluid reactions are both negative, he is eligible for marriage and may then be classified as "cured." The physical examinations made during the parole period should consist of search not only for cardiovascular disease or signs of central nervous system involvement but also for signs of cutaneous or mucous membrane recurrences. The mucous membranes, genitalia and especially the posterior side of the scrotum should be reexamined at each visit.

EFFECTS OF DICHLOROBENZENE

To the Editor—I am interested in whether or not a person can be harmed by dichlorobenzene. I have a patient who was overcome in a home being treated by a termite destroyer (dichlorobenzene). I saw her two days later when she complained of nausea, shortness of breath and sleepiness. She continually yawned while in the office. Hospital laboratory work showed only a lowered carbon dioxide combining power of blood plasma 43 per cent. One week after being overcome she had a hematuria for two days. Two weeks have elapsed and she still complains of weakness and some shortness of breath and pain in the back between the scapulae. I have read the articles in THE JOURNAL of Oct. 13, 1934 and March 23, 1935. Any further information on this subject that would enable me to treat the patient more scientifically would be appreciated. The method used in destroying the termites is spraying of liquid under pressure into the wood.

JACOB P. NILL, M.D. Pennsylvania.

ANSWER—Chlorobenzenes have been held responsible for a number of poisonings (Kemper H. Paradichlorobenzene, Insecticide Especially for Use in Houses, *Ztschr. f. Gesundheitsh. u. Stadhyg.* 24:291 [July-Dec.] 1932; Wybert, E. Poisoning of a Child Two Years Old by Puran, Cleaning Fluid Containing Monochlorobenzene, *Schweiz. med. Wchnschr.* 64:561 [June 16] 1934). On the other hand, dichlorobenzene has found some use in therapy (Bertucci, E. A. Dichlorobenzene Terpene Compound Vapor in Hemoptysis, *New Orleans M. & S. J.* 84:620 [Feb.] 1932). The chlorination of benzene lessens the toxicity of benzene itself. Although some variations in toxicity may arise, depending on the position of the introduction of the chlorine—that is, ortho, meta or para—the demarcation is not clear. Apparently the para position is associated with a greater toxicity, and it is this product which has enjoyed extensive use as a disinfectant and as a disinfectant. It is believed that the chlorinated benzenes assert a more active narcotic action than benzene and conversely are less destructive of the cellular elements of the blood. Some of the chlorinated benzenes are solids and are insoluble in water. This necessitates in some instances the use of solvents which themselves may be highly

toxic. Much of the literature centering about these compounds does not differentiate between the monochlorobenzene and the dichlorobenzene, nor is the position of the introduction of the chlorine often specified. Furthermore, the literature on this topic is confused through the fact that published articles refer without thorough definition to chlorinated compounds into which the nitro group has also been added. In spite of many opportunities for discrepancy, warrant appears to obtain for mentioning, as the chief manifestation of the action of chlorobenzenes, headache, dizziness, shortness of breath, cyanosis, hematuria and methemoglobinemia. The demonstrable lesions appear to occur chiefly in the blood, along the urinary tract and in the nervous system. In very acute poisoning, unconsciousness is characteristic. No treatment is well established for poisoning by chlorinated benzene. Various statements may be found indicating that the treatment is the same as for benzene poisoning. In the treatment of benzene poisoning, transfusions have been used, as well as heliotherapy, lecithin compounds and liver extracts. In the case of poisoning by chlorinated hydrocarbons in general, high calcium therapy has proved to be of some worth. In the very early stages, abstinence from alcohol is desirable.

REMOVAL OF SKIN STAINS

To the Editor—I would appreciate it if you would give me some information concerning the removal of dark brown stains on the face following contact with some liquid. This patient does not know what it was but it has the appearance of a sulfuric acid stain. The accident occurred March 28 and the stain on the skin did not appear until April 25. Can you give me any information with regard to removing a sulfuric acid stain? What is the likelihood of its being permanent? If this stain can be removed can you give me some idea as to length of time required? A patient's face was burned by an electric flash resulting from a short circuit of a 4600 volt line. Ointment cream was applied to the burn for several days. I understand that this cream contains phenol, camphor and aristol. I saw the patient seven weeks after the accident. At this time the skin was entirely healed and perfectly smooth. One half of the face which came in contact with the flash is stained a light brown. What is the prospect of permanence here and what would you suggest for its removal? Please omit name.

M D Massachusetts.

ANSWER—Pigment formed in the skin may be either (1) iron-free melanin formed by the epithelial cells or (2) iron-containing pigment derived from the blood which has in some way escaped from the blood vessels into the tissues. Other kinds of pigment may be introduced into the skin from without or be carried to it by the blood.

A sulfuric acid burn destroys tissue, which is sloughed off, leaving, if superficial, smooth skin or, if deep, more or less scar. The area may be pigmented in either of the ways mentioned. Pigmentation beginning a month after the injury, however, is almost certainly of the first kind. This can be removed in certain cases, but when it is the result of an inflammatory reaction as in this instance, it is often resistant and apt to recur after removal.

Bleaching may be tried. Perhydrol, a 30 per cent solution of hydrogen peroxide, may be used as follows: perhydrol, 2 cc., wool fat, 12 Gm., petrolatum, sufficient to make 20 Gm. Apply this to a small area once daily until an inflammatory reaction occurs, then stop it and wait for the dermatitis to subside. After this area is somewhat lighter, treat another in the same way. If there is no result, the ointment can be made stronger.

If more vigorous measures are necessary, carbon dioxide snow mixed with acetone may be tried. This allows a slight degree of freezing with less danger of causing a sharply defined spot, so hard to avoid when the pencil of snow is used.

The Jarisch bleach, ammoniated mercury, bismuth subnitrate and barium sulfide of each 1 part, ointment to 30 parts, may be spread on the area and allowed to remain over night. Strong applications are not advisable for fear of adding to the pigmentation. No definite length of time can be given, but cautious work will require several months at least, if the preliminary trial is satisfactory enough to warrant further treatment.

In pigmentation of the second kind the possibility of hematogenous pigment must be considered. If this is the case, nature will slowly remove it. More likely as in case 1, the pigmentation is melanin and it is probable that efforts to remove it will not be successful. A trial of the remedies suggested for case 1 is in order, however. The patient is impatient naturally and the methods mentioned may be tried on a small area and if successful applied to the whole area.

"Obtundia cream" was mentioned in *Queries and Minor Notes* in *THE JOURNAL*, Feb. 11, 1933. It is thought to contain camphor and metacresol which do not cause pigmentation. Its composition is unknown, however, and manufacturers of such nostrums often change the composition without notice.

NEUROPSYCHIATRIC DIAGNOSIS

To the Editor—Two years ago a woman aged 28 developed a diarrheal stool contained blood and mucus. Repeated stool examinations were made for *Amoeba histolytica* but was not found. In several weeks she developed an acute condition of the abdomen and was hospitalized and seen by five consultants who all recommended an exploratory laparotomy. This was done and nothing was found except a slight peritoneal injection extending for about 8 inches from the ileocecal junction. The appendix was removed and found to have some round cell infiltration. She had an uneventful convalescence and the diarrhea stopped three weeks after which it recurred and she noticed moderate sharp pains in the abdomen and also complained of severe pains in the chest. Stool examinations were again done and finally *Amoeba histolytica* was found. Since that time she has had every known treatment for amoebic dysentery and the colitis has cleared up but she has gradually developed a generalized hyperesthesia of the skin which is more pronounced on the left side. This has become so severe that the light pressure of a stethoscope causes an intense pain. The only time she is free from it is when standing on her feet unclothed. The pressure of her body against the bed causes pain that makes it impossible for her to sleep. She has been roentgenographed many times and her basal metabolic rate is 115. She has a daily fever up to 100 F and her pulse is consistently around 120. She has been examined thoroughly by a proctologist, two internists and a leading neurologist. One internist believes that the symptoms are due to the dysentery and the other believes that she has an arthritis of the spine in spite of the negative roentgenograms. The neurologist is of the opinion that there is a visceral nerve imbalance and states that not only has he never seen a similar case but he has never heard of one and offers no suggestions as to a possible cure. The neurologic examination was entirely negative. She has had all the usual sedatives and hypnotics, but even the morphine will not relieve the pain. She has had streptococcus vaccines and tissue extract. Have you any suggestions to offer that could possibly relieve this pain? Please omit name.

M D, Washington.

ANSWER—The absence of any positive neurologic signs and the bilateral nature of the symptom, even though it is worse on the left side, does not fit in with any known neurologic disturbance of an organic nature. The possibility of a thalamic syndrome as described by Head and Holmes must be borne in mind, but the query definitely states that the neurologic examination was entirely negative. If this is true, one must consider the patient to have a functional or psychogenic hyperesthesia. A psychiatric study of the patient should be made and it is suggested that one of the possible methods of attack be hypnosis.

TOLUENE POISONING

To the Editor—What are the symptoms, prognosis and treatment of toluene poisoning? Is it possible for a man working with toluene for two years to develop an acute poisoning or is it always due to an accumulation?

JACOB LEVITT M D Detroit.

ANSWER—Toluene (toluol) poisoning may arise either as an acute or as a chronic disease, and the two may coexist. The symptoms of toluene poisoning are very similar to those from benzene. Given equal exposure, narcosis from toluene is perhaps more likely to arise than from benzene. Acute toluene poisoning has as its chief manifestations those commonly associated with an asphyxiating substance. Dr. Alice Hamilton's description of acute benzene poisoning (*Benzene* [Benzol] Poisoning, *Arch. Path.* 11:434 [March], 601 [April] 1931) extensively applies to its homologue toluene so far as manifestations are concerned. From McCord and others in their brochure "Benzol (Benzene) Poisoning" the following excerpts are derived, which though descriptive of the acute action of benzene indicate the type of acute action of toluene.

High concentrations of benzene may lead to immediate pronounced effect upon the central nervous system culminating in violent convulsions and narcosis.

After death from acute benzene asphyxiation there may be no demonstrable anatomical changes or there may be evidence of hemorrhagic engorged blood vessels, noncoagulability of the blood, particularly if the victim lives several hours after exposure.

At autopsy an odor of benzene may be detected but not invariably. Before death an odor of benzene on the breath is not unusual.

Irregularly benzene may be recovered from tissues through distillation methods. Based upon experimental work methods have been described for the detection of benzene and phenol during acute poisoning.

Phenol or substances chemically similar to phenol have been found in the urine, but there have been instances of failure to find it in the urine.

Toluene and xylene probably are capable of producing acute poisoning more readily than benzene. No difference in manifestations is known to exist.

The prognosis for either acute or chronic toluene poisoning in severe form is not good. If the patient survives severe acute poisoning for one week the prognosis may be better than in the case of severe chronic poisoning because of the damage in the latter instance that is brought about to the liver and tissues. In chronic poisoning a prime hazard to a fatal outcome resides in the marked susceptibility to infection. At times fatalities are produced as a result of infection.

orrhages into the various organs, such as the heart or brain, may lead to permanent abnormality, even though the blood picture may return to normal and even though the marked susceptibility to infectious processes may have disappeared. A good prognosis for either acute or chronic toluene poisoning is not warranted until late in the course of the disorder, when it appears that substantial gains have been made. The treatment of toluene poisoning is the same as for benzene poisoning and is far from satisfactory. Davis sums up the trend of treatment thus:

Elimination aeration treatment of gastric disturbances treatment of anemia, supportive measures for the heart and kidneys stimulation of the blood forming organs by iron compounds x-ray of long bones liver and spleen substances and transfusions nourishing foods with excess of fats increased calcium intake

McCord (*ibid*) furnishes additional procedures as follows

The person suffering from any form or degree of severity of benzene poisoning should not be permitted to continue exposure to that substance. Hospital care is indicated for all systemic poisonings from benzene, but it is not necessary for the more frequently encountered dermatitis. Acute poisoning (asphyxiation) may require artificial respiration supplemented by the Henderson and Haggard inhalator if available. Muscular exertion should be avoided. The rescuer of an unconscious man in enclosed areas such as a tank car apparently is more likely to die than the unconscious man who quietly entered that state. Cardiac and respiratory stimulants may be required. Lecithin emulsion (5 cc. of a 10 per cent strength) has been administered intravenously to advantage. Convalescence should be extended to avoid complications. Chief among these are pneumonia, bronchitis gastritis and cystitis. Acute benzene poisoning may be produced by the oral intake of benzene in error or for suicidal purposes. Emptying of the stomach is indicated. Profound local irritation is prone to take place. The administration of alkaline fluids such as milk is commendable. In the chronic case hemorrhage and proneness to infection largely determine the treatment. Blood coagulants are rarely of value. Prompt transfusions are desirable whenever hemorrhage is present even though the general situation is not grave. Under no circumstances should the severely poisoned victim of benzene be subjected to such procedures as dental extractions tonsillectomies etc. The judicious use of liver preparations is indicated. Those practices that attend the proper use of liver in other severe anemias should govern its administration. Sunlight natural or artificial has proven valuable

BRUCELLA ABORTUS INFECTION

To the Editor—My inquiry concerns *Brucella abortus* infection. A mother of two healthy children with all past history negative, becomes pregnant about the time that a herd of cows from which she received her milk supply is diagnosed as being infected with *Brucella abortus*. She is delivered of a stillbirth of eight months. The mother's antepartum history is negative. What is the method of procedure in determining whether the mother is infected? Is there any particular time that an abortion miscarriage or stillbirth may occur?

LOUIS H. SWETZALITSCH M.D. Coraopolis Pa

ANSWER—In 1917 de Forest (*Am J Obst & Dis Women & Child* 76 221 [Aug.] 1917) reported eleven cases of abortion in women in which there was strong circumstantial evidence that the occurrence of abortion was related to contagious abortion of cattle. In several instances the women aborted during the time of an epidemic of contagious abortion among the cattle on their farms. There is evidence that *Brucella* organisms occasionally exhibit a predilection for the genital tract of human beings as in cows or bulls. Kristensen (*Ann de med* 26 339 [Nov.] 1929) isolated the abortus variety of the organism from the exudate which covered the uterine site of the placenta of a seven months fetus. Carpenter and Boak (*THE JOURNAL*, April 11, 1931, p 1212) recovered *Brucella* from the tissues of a human fetus which was aborted at the end of the fourth month of gestation. Frei (*Schweiz med Wchschr* 59 334 [March 23] 1929) isolated *Brucella* from the vaginal discharge of a woman who had aborted ten days previously. Simpson, Harbinson and Ey have found strongly circumstantial clinical and serologic evidence that *Brucella* infection was a factor in the production of several cases of human abortion. Cornell and DeYoung (*Am J Obst & Gynec* 18 840 [Dec.] 1929) tested the blood serums of 1,015 pregnant women in Chicago. Of this number none gave definitely positive reactions and in only five instances were there weakly positive reactions. Their conclusion was that brucellosis is not generally prevalent in pregnant women in Chicago. In this connection it should be noted that most of the milk supply of Chicago is pasteurized. Adequate pasteurization destroys *Brucella* organisms. It seems quite probable that brucellosis is an occasional cause of human abortion, particularly among women who live on farms where they have direct contact with infected animals as well as among women who consume unpasteurized milk and other dairy products. The agglutination test is perhaps the simplest method of determining the presence of the disease. In about 5 per cent of individuals with

brucellosis, antiabortus serum agglutinins failed to develop. If the agglutination test is negative, or positive in low titer, a diagnostic skin test may be done (Diagnosis of Undulant Fever, *Queries and Minor Notes*, *THE JOURNAL*, May 12, 1934, p 1633). If the agglutination test and skin test are negative, it is quite probable that the patient does not have brucellosis. There is no evidence to indicate that abortion, miscarriage or stillbirth may occur from this cause at any particular period during gestation.

CONJUGAL SYPHILIS

To the Editor—A man aged 33 and his wife, aged 32 came to me to be treated for syphilis. He gives a history of a penile lesion when 19 years of age which rapidly healed and the incident was forgotten until six years ago when he developed another penile lesion which he attributed to a scratch from a broken B V D button. He consulted a physician who suggested a Wassermann test although there were no secondary symptoms. The doctor did say he believed it was a chancre. He did not begin treatment and it spontaneously healed. Both the man's and his wife's blood at this time are 4 plus and have been for the past two years. Two years ago because of nervousness he again consulted the same doctor. Both he and his wife were treated. He was told that he had Malta fever as well as syphilis. He had several courses of nearsphenamine and a bismuth compound and yellow mercurous iodide by mouth. His blood is still 4 plus. The wife is in good health. They have a son 11 years old who has a negative Wassermann reaction and no syphilis. Five years ago the wife was about six months pregnant and began to flow. She was ordered to bed for a month. She had labor pains and was taken to a hospital and her doctor (an osteopathic physician surgeon) did a cesarean section. The child was apparently normal but died a short time after birth and because of her exhaustion she was given several syringefuls of whole blood fresh from her husband. It was injected into her left breast. Two years ago at the same time as her husband she had a Wassermann test and both were 4 plus as they are at this time. She had three nearsphenamine injections and had a very severe arsenical dermatitis develop. A single injection of sulfarsphenamine given a month later caused another similar reaction. Neither has ever developed secondary symptoms and the doctor told them he did not believe they ever would have negative Wassermann reactions but advised that they take a course of treatment once a year. I would appreciate your giving me an outline of treatment, a prognosis and anything else that you believe would be helpful. Please omit my name.

M D California

ANSWER—The history of a penile lesion or the history that no penile lesion was ever noted by a patient should have no weight in the decision as to whether or not a patient should be treated for syphilis. The fact that this couple have had repeatedly positive Wassermann reactions is highly suggestive that they both have syphilis. As several pertinent facts are not given in the query it is quite impossible to offer a prognosis or adequately outline treatments for these patients. It would be advisable to examine the spinal fluids of both patients and to examine them both for evidence of cardiovascular, visceral or other evidence of syphilis, and also to record if possible the exact amount of treatment of all types that the patients have received. The details and type of the subsequent treatment will depend on the result of these examinations but even though the cerebrospinal fluid and clinical examination are both negative the patients have not had a sufficient amount of treatment and both are sufficiently young to warrant intensive treatment with the arsphenamines and preparations of bismuth. If, on the other hand, the spinal fluids were positive or visceral evidence of syphilis is elicited, the treatment should be given according to the type of complication noted.

SALT RETENTION IN PEMPHIGUS

To the Editor—Would it be out of order for me to ask you to ask the writer of the query on pemphigus in *THE JOURNAL*, Oct. 19 1935 about his statement that salt retention is a feature of pemphigus? I should like to know the source of his information for that statement. I have never noticed any such retention in the study of my patients, but if it does occur I think it is a very important point.

M F ENGMAN M.D. St Louis.

ANSWER—There is plenty of authority for the statement that salt retention occurs in pemphigus. Riecke, (in the *Handbuch der Haut- und Geschlechtskrankheiten*, 7/2 Berlin, Julius Springer, 1931) devotes eight pages (511-518 inclusive) to a review of the literature of this subject. The phenomenon was first noted by K. Krieger in 1872. He found hardly any sodium chloride in the urine of a woman, aged 23, with pemphigus foliaceus. Fodor in 1895 in a case of pemphigus in which the whole body was involved, found hardly a fifth of the normal amount of sodium chloride in the urine. Since then there have been many reports, most of them agreeing that, during severe attacks of pemphigus, salt excretion in the urine, feces and sweat is at a minimum. Cassaët and Michelson in 1906 stated their opinion that salt retention means a general alimentary

intoxication and that a salt-free diet causes improvement of the pemphigus with increased elimination of salt in the urine. They also thought that there was with this increase a greater elimination of the toxins. Vanrobert in 1930 obtained the same results, with much salt in the diet there was retention. With a salt-free diet there was a gradual return to balance between intake and elimination. Moreinis and Medvedev in 1927 at postmortem examination in a case of pemphigus found salt retention in all organs except the spinal cord and the skin. Sabrazes and Torlais in 1929 warned against the use of a salt-poor diet, especially in cachectic cases, because it has not been proved that salt retention is due to kidney dysfunction.

Salt retention is not due to storing of salt in the fluid of bullae, for several authors have reported marked retention of salt in cases in which only mouth involvement before the skin involvement had occurred. In 1926 Urbach found low salt elimination with a normal amount in the blood, and in four cases without increased salt in the diet there was an increase in the sodium chloride content of the skin. He thinks that salt retention is a protective function with increase of albumin destruction. Skin involvement, disturbance of sodium chloride metabolism and albumin destruction are coordinate symptoms of pemphigus.

Leszczynski and Blatt in 1927 showed that sodium chloride retention fluctuated with eosinophilia, temperature and variation in severity of the eruption and that thirst, as manifested by shortened time of resorption of a wheal made with 4 per cent sodium chloride, also ran parallel with these.

Riecke's summary accords salt retention no place in the etiology or pathogenesis of pemphigus. It may be a protective phenomenon, retention of sodium chloride sparing albumin. This may be only apparent, however. Salt is retained during the florid period, increase of salt in the diet lessens excretion of salt in the urine, and lessening salt in the diet improves salt elimination. It is not peculiarly specific for pemphigus but occurs in other diseases in which tissue is destroyed. Riecke suggests that further studies should be made of the effect of increase of dietary salt during latent periods and of endocrine anomalies in cases of pemphigus.

ADMINISTRATION OF DIGITALIS

To the Editor—In a recent publication a well known cardiologist discusses a case in which a diagnosis was made of chronic rheumatic heart disease (inactive) with mitral stenosis and insufficiency, cardiac hypertrophy with auricular fibrillation and congestive failure dependent edema, ascites and right hydrothorax. After the congestive failure had been cleared up by bed rest, digitalis and salyrgan the patient was discharged from the hospital. A rigid cardiac regimen was instituted and the patient was advised to take tincture of digitalis intermittently 15 cc of standardized tincture (15 cat units) three times daily for two consecutive days each week. The patient's weight was 120 pounds (54 Kg). If the patient had left the hospital fully digitalized she would have excreted most of her digitalis within the next five days before the 9 cat units of tincture was administered over a two day period. Although this dose is more than is usually necessary to maintain digitalization I do not believe it can have any effect on a patient already digitalized. I would appreciate an opinion on the following: Would this method of administering digitalis have any appreciable effect in preventing a recurrence of congestive failure? Would it have any effect in reducing a pulse deficit? Would these effects be maintained during the five days digitalis was not taken? Digitalis is often given in single doses of from 1 to 5 cat units subcutaneously or intravenously when it is believed that the heart is failing as during the course of an acute infectious disease or after an extensive surgical procedure. Do such single doses exert any appreciable effect on the heart or circulation of patients not already fully digitalized? What is the present opinion on the daily use of minimal doses of digitalis (i. e. less than 1 cat unit daily) as a heart tonic or to prevent the onset of congestive failure? Please omit name. M. D. New York.

ANSWER—The advice given in this case was doubtless based on the rate of digitalis excretion as observed during the patient's stay in the hospital and was also probably given tentatively, to be changed from time to time as conditions indicated.

The rate at which digitalis bodies are detached from the heart muscle and excreted varies so much with each individual that no rules as to a maintenance dose can be formulated. It is moderately constant for the individual but not so constant that it does not have to be watched from time to time. The patient can successfully be taught to maintain an adequate dosage. The physician should be guided by the clinical results and not by the pulse deficit. Cases occur in which the minute value is greater and the heart more efficient with a greater pulse deficit or in whom evidences of passive congestion occur when the rate is slowed and there is no pulse deficit.

The dosage given in this case was quite enough to maintain the desired effect. Some cases might need more, some might need less. It might be better to give daily small doses sufficient to maintain the digitalis level but it is not important.

It is probable that the single doses given as stated have an effect in cases in which digitalis has not previously been given. They at least do no harm, as larger doses might do so definitely indicated.

The use of minimal daily doses of digitalis as suggested is a matter of opinion, and evidence as to the advantage or disadvantage is not clearly substantiated.

ONE DOSE ANTIRABIES VIRUS—DISTEMPER SERUM

To the Editor—Please give your opinion as to the value of the one dose antirabies virus which is given to dogs as a preventive of rabies. I am interested in this from a public health standpoint. What is the value of distemper serum?

M. D., Georgia

ANSWER—According to available information, the preventive inoculation of dogs with one dose of phenolized vaccine against rabies is still in the experimental stage. The method is not established as uniformly successful and reliable in practice though its use is recommended by many veterinarians.

So far as is known, no serum has been developed against distemper, but the vaccine of attenuated living virus of Landau and Dunkin appears to be effective in preventing the disease.

USE OF TETANUS ANTITOXIN

To the Editor—In the discussion on vaccination by Dr. J. P. Leake in THE JOURNAL Oct. 27, 1934, page 1275 the final thought seems to indicate that the use of tetanus antitoxin in Dr. Leake's opinion should be universal in the case of any wounds. I know that it is considered by some authorities that all persons injured in automobile accidents should receive immunizing doses of tetanus antitoxin. I know that many men hardly dare fail to give an immunizing dose in any puncture of the foot particularly but in a workmen's compensation case seen a few years ago the patient had a serum reaction and the medical adviser of the board stated that it was not current practice to use immunizing doses except in puncture wounds in the environment of stables and similar places. He said that it was permissible to use them but rather better judgment to refrain from using them. One is impressed by the rarity of tetanus when considering the frequency of wounds of all types and even of puncture wounds that occur in civil life. I should be glad to see an authoritative discussion of this subject. I have a feeling that perhaps commercial interests are to some degree responsible for a lot of sub-tetanic serum used.

ELMER S. BAGNALL, M.D. Groveland, Mass.

ANSWER—The tetanus bacillus and its spores are so widely distributed in nature that any accidental wound may become infected. It is true that in civil life only a small percentage of such wounds are followed by tetanus, but unfortunately there is no way of telling beforehand whether tetanus will develop from a given wound. Tetanus is a deadly disease. While tetanus antitoxin will prevent tetanus, it has little curative effect on the established disease. In view of these facts the physician on whom falls the duty to treat first a wounded person cannot expect to escape blame should tetanus develop in a case in which he ventured "to take a chance" and not inject antitoxin serum.

CHANGES IN NEW U. S. PHARMACOPEIA

To the Editor—I have been informed that there have been certain changes made in the new U. S. Pharmacopeia since its issuance. Will you kindly state whether or not these will affect the prescribing physician seriously?

L. W. Wierce

ANSWER—There have been a number of corrections in the U. S. Pharmacopeia XI. In compiling a book of such magnitude, typographical errors are bound to creep in. Many of these have been corrected and are of a nature which does not affect the prescribing physician directly. The essential changes in which the physician should be conversant are as follows:

1. The new Pharmacopeia directs that distilled water shall be used in all formulas. This requirement has been revised to permit the use of natural water of good quality as an alternative to distilled water in the extraction of U. S. Pharmacopeial drugs and in the manufacture of Resin of Podophyllum and of Saponated Solution of Cresol.

2. Dextrose. After the section Tests for Purity (p. 141) the following note has been added: "In preparing aqueous solutions of Dextrose it is permissible to use a dextrose which does not conform to the official requirements for water of hydration provided the product meets all other official requirements for purity and also provided suitable allowance is made for difference in water content."

3. Diluted Ferric Trinitrate. The dosage (p. 149) has been changed from 0.3 Gm. (5 grains) to 0.03 Gm. (1/2 grain). [Typographical error.]

4. Solution of Irradiated Ergosterol. The synonym "Vitamin D₂ in Oil" has been added (p. 203).

Minnesota April Report

Dr Julian F Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held in Minneapolis, April 21-23, 1936. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Sixty-two candidates were examined, all of whom passed. Five physicians were licensed by reciprocity and 1 physician was licensed by endorsement. The following schools were represented

Book Notices

Epitome of the Pharmacopoeia of the United States and the National Formulary with Comments Prepared for the Use of Physicians under Authorization of the Council on Pharmacy and Chemistry of the American Medical Association by a Committee of Council Members Robert A. Hatcher Ph. M. M.D. Professor of Pharmacology Emeritus Cornell University Medical College Chairman of the Committee Ernest E. Irons Ph.D. M.D. Clinical Professor of Medicine Rush Medical College Torald Sollmann M.D. Professor of Pharmacology and Materia Medica School of Medicine Western Reserve University and Paul Nicholas Leech Ph.D. Secretary of the Council on Pharmacy and Chemistry Fifth edition Cloth Price 60 cents Pp 240 Chicago American Medical Association 1936

The new (fifth) edition of this book differs considerably from the preceding editions both in content and in appearance. The present volume contains only those items which are official in either the new (eleventh) Pharmacopoeia of the United States or the new (sixth) National Formulary. The result is that 343 items are omitted 202 are newly admitted and 118 appear under new names. The same care has been used in revising the sections on actions and uses of the retained items as in formulating those sections for the new admissions. This edition is the first to include the italicized statements of caution found in the Pharmacopoeia and National Formulary. The make-up has been improved by more uniform spacing of sections, preparations and items. The older plain red cover has been replaced by a green cover with the title on both the cover and the back bone. The newness of the book is further apparent in that those items which are to appear in the forthcoming edition of Useful Drugs are designated by a star. This new summary of the two official drug standards as extracted and augmented under the supervision of the Council on Pharmacy and Chemistry should prove even more useful than preceding editions.

Bacteriology in Relation to Clinical Medicine Theoretical and Applied For Students Laboratory Workers and Practitioners in Medicine and Public Health By M. N. De M.B. M.R.C.P. Professor of Pathology Medical College of Bengal Calcutta and K. D. Chatterjee M.B. Medical Registrar Medical College Hospitals Calcutta Cloth Price 30s. Rs 15/- Pp 599 with 276 illustrations Calcutta The Statesman Press 1935

This volume essentially a textbook of bacteriology presents data concerning micro-organisms commonly associated with disease in man. The several chapters describe the individual organisms their identifying biologic characteristics and their relation to disease, and in addition consider the pathology of the disorders induced by the pathogenic agents. The minutiae of the technical procedures of a bacteriologic laboratory, such as the preparation of culture mediums bacterial stains serologic tests and animal inoculations commonly used for diagnostic purposes are described in detail. In this respect it is the equivalent of a laboratory manual. Comments on pathogenesis and descriptions of pathologic processes are presented in condensed form but are not elaborated to the extent of the bacteriology. The combining of bacteriology and the related pathology is the special feature that is stressed by the authors. Bearing in mind that the book was designed for "students laboratory workers and practitioners in medicine and public

health," one finds the subject matter treated in an orderly and elementary way favorable to the initiation of beginners in the subject. The information is presented in simple and clear phraseology and includes, with a few exceptions, the results in current literature. As might be expected from the residence (Calcutta) of the authors, their consideration of the infectious agents and processes prevalent in India reflects an intimate experience, which makes the chapters devoted to these subjects the best of the book. The laboratory methods, described in detail, consist of many in universal use and others that are less regularly adopted in this country. There are numerous illustrations, many of which are colored. The selection and presentation of illustrations are excellent and form an unusually pleasant, as well as informative, feature of the book. The paper, type and format are to be commended for promoting the general attractiveness of the volume. Special students and investigators will find that, in some of the subjects, simplicity and brevity have been maintained at the expense of important though perhaps not elementary, points of view, and that the disposition of other material with paragraphic generalizations leaves much that is significant untouched. There is no bibliography.

Physical Therapy for Nurses By Richard Kovacs M.D. Clinical Professor and Director of Physical Therapy Polytechnic Medical School and Hospital New York. Cloth Price \$2.75 Pp 286 with 18 illustrations Philadelphia Lea & Febiger 1936

Realizing that nurses are constantly called on to give physical therapy treatments, the author has prepared this book with the idea that it will serve primarily as a manual for nurses. The book is divided into nine chapters, comprising a general survey of physical measures, simple physics, heat, sunlight, electricity, water, massage, exercise, and institutional practice. The chapter on general physics deals primarily with physical energy as applied directly to physical therapy. The language used should be readily understandable to those who have had a course in high school physics. The chapter on sunlight deals with the radiation not only from the sun but also from artificial sources. The dangers are pointed out that may befall the uninformed when using physical therapy equipment. Of particular value to nurses is the information on heat, massage, hydrotherapy and exercise. It is highly probable that a nurse may use these practical forms of treatment more than any other physical therapy agent. The technic of hydrotherapy procedures such as baths, packs and compresses, which are regular nursing procedures is given in detail. The technic of massage and its descriptive movements are effectively recounted. The chapter on exercise, prepared by Dr. Madge C. L. McGuinness deals with muscle training, athletics, formal gymnastics, and the physiologic effects of exercise. The final chapter, on physical therapy in institutional practice, contains information on personnel, relation of the physical therapy department to other departments, location, space, equipment and records. The author suggests the amount of equipment required for a physical therapy department in a clinic handling from thirty to fifty cases daily—a courageous undertaking. He points out that the appliances should be accepted by the Council on Physical Therapy of the American Medical Association. He proposes that the apparatus need not be complicated and suggests that the simpler equipment be used whenever possible. The clear compact information contained in this volume should be of great help to graduate nurses who have not had instruction in this type of treatment. It should be of particular value also to teachers of physical therapy in nurses training schools.

La syphilis gastrique. Etude clinique Par Anastase Landau Chef des hôpitaux de Varsovie et Joseph Held médecin du 1^{er} Service de l'Hôpital Wolski à Varsovie Paper Price 32 francs Pp 140 with 15 illustrations Paris Masson & Cie 1936

The authors describe what is called "syphilitic gastritis" in fifty-eight of a hundred cases of late syphilis. Their criteria for this diagnosis are hypoacidity or anacidity together with a delay or absence of the secretion of neutral red in the stomach contents the dye being injected subcutaneously. Similar studies in a control group of normal patients are lacking. The organic disease of the stomach due to syphilis is next considered. Three types of lesions are said to exist ulcerative, the stomach single or multiple pseudoneoplastic and plastic. The improvement obtained with antisyphilitic treatment

ment forms practically the sole basis for their diagnosis of stomach syphilis. A section is devoted to gastric complaints in neurosyphilis, especially the gastric crises of tabes, and what is termed 'syphilitic gastric radiculitis.' This book offers interesting reading, and though it presents little that is new it is of value in directing the attention of the internist to the possible manifestations of gastric syphilis.

A Systematic Handbook of Volumetric Analysis or the Quantitative Determination of Chemical Substances by Measure Applied to Liquids, Solids and Gases Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography etc. and for the Valuation of Substances Used in Commerce, Agriculture and the Arts. By Francis Sutton F.I.C. F.C.S. Twelfth edition revised with numerous additions by A. D. Mitchell D.Sc. F.I.C. Scientific Assistant University of London. Cloth. Price \$10. Pp. 631 with 128 illustrations. Philadelphia: P. Blakiston, Son & Co. Inc., 1935.

This volume enjoys an enviable reputation as a standard work in the field of volumetric analysis. After the three score and ten years since the first edition was published, the volume is now found in its twelfth edition. Its age is proof of its merit and the service it has rendered, but during this span of years volumetric analysis has grown to be a large, unwieldy mass of information. It is therefore undoubtedly true that this volume does not cover the field of volumetric analysis now as thoroughly as did the first volume seventy years ago. In this connection the authors suggest in the preface to this edition:

It is regretted that space does not permit of the inclusion of a section on Microchemical Titration, but the advances in this region have been so great as to render this impracticable.

For general methods it is as valuable as ever. Discussion of these methods and references to the original papers are particularly valuable. In many cases specialized methods will have to be sought elsewhere.

Medizinische Praxis. Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, Leitender Arzt der Medizinischen Klinik des Rudolf Hess Krankenhauses, Dresden. Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Städtischen Krankenhauses, Dresden. Friedrichstadt und Prof. Dr. K. Warnke, Direktor der städtischen Frauenklinik zu Dresden. Band IX: Blutung und Fluor. Von Prof. Dr. Hans Runge, Direktor der Universitäts-Frauenklinik, Heidelberg. Second edition. Paper. Price 7 marks. Pp. 117 with 18 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1936.

This small book is one of a series of monographs written expressly for general practitioners on a variety of medical topics. It is full of valuable information on the subjects of uterine bleeding and vaginal discharges. In the discussion of uterine bleeding the author includes the most recent advances made in the field of endocrinology as they pertain to his subject. The section dealing with the treatment of menstrual disturbances is especially useful because of the author's sane attitude on the use of endocrines. The chapter on leukorrhea likewise contains sound advice concerning therapy. The booklet should prove useful to any physician who desires a comprehensive knowledge of uterine bleeding and vaginal discharges.

La rate en pathologie sanguine. Par Emile Houcke, médecin des Hôpitaux de Lille. Préface de M. le Professeur Curtis. Paper. Price 45 francs. Pp. 167 with 20 illustrations. Paris: Masson & Cie, 1936.

This monograph concerns itself with the histopathologic, clinical and therapeutic aspect of enlarged spleens. The work is based on original studies previously published by the author and for the most part represents his personal observations. The text is divided into four parts. The first part is devoted to the hematopoietic reactions of the spleen from both experimental and anatomopathologic points of view. The following division is concerned with splenomegaly accompanying the reactions of the reticulo-endothelial system. The third is a consideration of the spleen in its relation to hemolytic anemias. The last chapter treats the circulatory disturbances in which the spleen may become involved. In this chapter the author presents an excellent discussion of Banti's syndrome. The neoplastic splenomegalies were not considered, as this phase of the subject was not included in the author's research program. The contribution is mainly from the anatomopathologic aspect of splenic reaction. With the aid of his histologic data the author has attempted to group the splenomegalies according to their morphologic alterations. Three general groupings have been adopted: hematopoietic, reticulo-endothelial and sclerotic. In

some respects the first two groupings overlap. In adopting such a general classification the author hopes to reduce the multiplication of types often found in a clinical grouping. The material is well presented and organized. The illustrations are in black and white. While the monograph does not solve many of the problems of splenomegaly, still poorly understood, it is a provocative and informative piece of work. The work should interest the clinician as well as the pathologist, for many of his therapeutic considerations are based on the clinical application of such data.

Formulary of the University Hospitals of Cleveland. The Babies and Childree's Hospital, the Leonard C. Hanna House, the Lakeside Hospital, the Maternity Hospital, the Rainbow Hospital. Revised by the Pharmacy Committee and Approved by the Medical Council. Paper. Pp. 81. Cleveland, Ohio: The University Hospitals of Cleveland, 1935.

The preparations in this loose-leaf formulary are selected from the Pharmacopeia, the National Formulary and New and Nonofficial Remedies. The inclusion of unofficial preparations is dependent on selection by the hospital pharmacy committee and subject to the approval by the medical council of the hospital. The items appear in prescription form with the amounts indicated metrically; they are therapeutically grouped. The book is superior to most hospital formularies in that the prescriptions are not individually numbered and it is of convenient size. Some of the official items included are designated U.S.P. or N.F., others are not. Available N.N.R. preparations appear in a separate list. Previous editions have been in use for almost ten years and this revision should serve its purpose well.

Measles. Report of the Medical Officer of Health and School Medical Officer on the Measles Epidemic 1933-34. London County Council No. 3180. Paper. Price 1s. Pp. 42. London: P. S. King & Son Limited, 1936.

This is the fourth report on measles in London, which there assumes epidemic form regularly every two years. The first part deals with the epidemic of 1933-1934 involving 12,896 cases with 712 deaths. Valuable statistical data are given in tables in the text and the appendix. Part 2 contains special papers. E. H. R. Harries writes on points of administrative procedure, Hilda Linford reports observations on otitis media in measles, J. E. McCartney discusses the preparation of adult and convalescent serum, and William Gunn and W. T. Russell report on the use of immune measles serum in the control of outbreaks of measles in hospitals, institutions and residential schools. The data (ten tables) concern 1,874 persons inoculated with convalescent serum or with adult serum presumed to contain measles immune substances. To secure complete protection, a minimum dose of 5 cc. of convalescent serum or 10 cc. of adult serum was given to children under 3 years of age within six days after exposure. For attenuation these amounts were given on or after the sixth day, or one-half these amounts earlier than the sixth, preferably about the third day after exposure. Children 3 years old and over received amounts of serum graduated according to age. Of the children inoculated with adult serum for prevention, a protection rate of 78.2 per cent was secured, with convalescent serum the protection rate was 80 per cent. The serum-treated patients had milder attacks, fewer complications and a smaller death rate than the controls. The report as a whole is a valuable contribution to the study of measles as a problem in public health. Why don't the departments of health in American cities publish reports of this nature?

Organic Chemistry. A Brief Introductory Course. By James Bryant Conant, President of Harvard University. Revised with the assistance of Alex. Tishler, Ph.D. Cloth. Price \$2.60. Pp. 293 with 27 illustrations. New York: Macmillan Company, 1936.

This textbook by James Bryant Conant, formerly Sheldon Emory professor of organic chemistry at Harvard University and now president of Harvard University, was written for use in a short course in organic chemistry. In the majority of cases it will be used by students who will take no more chemistry. The author attempts to arouse interest by brief descriptions of the nature and manufacture of certain well known organic compounds of commerce. There is an abbreviated discussion of biologic products such as the more common glandular principles and of the vitamins.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts Operation of Dental Office by Layman Unlawful—Carroll, a layman, owned and operated a dental parlor in Michigan, the dental services being rendered by three licensed dentists in his employ. He was convicted of violating section 15 of the dental practice act, which makes it unlawful for any person, not licensed to practice dentistry, to—

operate or be a partner in the operation of or control as proprietor manager or otherwise or to have any financial interest in the proceeds or receipts of or from, other than compensation as employee in the usual course of business any room, office or dental parlor where dental work is done provided or contracted for

He appealed to the Supreme Court of Michigan

Carroll contended that the section of the dental practice act quoted violates the due process clauses of the state and federal constitutions in that it deprives him of a right to have a proprietary interest in a dental parlor, if all dental work is done by licensed dentists, and that the prohibition does not even remotely promote the public health and welfare. It is a well known fact, answered the Supreme Court, that the services rendered in the profession of dentistry are personal and call for knowledge in a high degree. To separate this knowledge from the power of control is an evil. Courts distinguish between professions and businesses. In the latter, individuals may engage in the common occupations of life, and laws which unnecessarily impair these rights must be held unconstitutional, but in the practice of a profession such as dentistry, which has to do with personal privacy and where the licensee must possess skill and character, it is as well within the police power of a state to prohibit the ownership and operation of a dental parlor by a layman as it is to prescribe the qualifications of those who engage in the practice of dentistry.

The Supreme Court accordingly affirmed the conviction of Carroll—*People v Carroll (Mich)* 264 N W 861

Workmen's Compensation Acts Rupture of Blood Vessel Attributed to Strain—The employee, while engaged with others in lifting a heavy pipe, felt a sudden 'burning sensation' from his left kneecap downward to the ankle. Total and permanent disability resulted. The district court, in a proceeding under the workmen's compensation act of Texas, awarded the employee compensation, finding that the strain had ruptured a blood vessel in the employee's leg. The insurance carrier appealed to the court of civil appeals of Texas, San Antonio.

There was evidence to show, said the appellate court, that the strain of lifting the heavy pipe resulted in the rupture of one of the blood vessels in the employee's leg and that the resulting incapacity was total and permanent. While several physicians testified that the employee's condition was due to varicose veins with which he had been afflicted for from five to twenty years that testimony did not overcome in the opinion of the court, the direct testimony of the employee and of his wife and son and daughter that he had never before the accident had any of the symptoms of varicose veins. Furthermore, two weeks before the accident as the condition of his employment the employer's physician gave the employee a thorough physical examination and pronounced him sound in health and fit for work. This evidence concluded the appellate court, was sufficient to support the trial court's finding and the judgment for the employee was affirmed—*United States Casualty Co v Larc (Texas)* 91 S W (2d) 465

Evidence Competence of a Chiropractor as a Witness—In this proceeding under the workmen's compensation act of Texas the trial court permitted over the objection of the insurance carrier a chiropractor to testify concerning the injuries sustained by the employee. The insurance carrier

contended that the witness, being merely a chiropractor and not a licensed physician, was disqualified from testifying concerning the condition in which he found the employee, who he treated for four months, and to give his opinion as to the cause and effects of that condition. The witness, said the court of civil appeals of Texas, on appeal, was a graduate of a San Antonio chiropractic school and of "the well known Palmer School," and had been in active practice for more than five years. We may take judicial notice of the fact, said the appellate court, known as a matter of common knowledge, that chiropractic, "a system, or the practice, of adjusting the joints of the spine by hand for the curing of disease (Webster) imports a study, knowledge and treatment of the human vertebrae, which includes the bones of the neck. The witness testified that he made a thorough examination of the injured man, shortly after the accident, which disclosed a "misalignment" of the "second bone of the vertebrae in the neck," and that this displaced bone pressed on the spinal cord, causing the condition in which he found the employee. The trial court, said the appellate court, did not abuse its discretion in admitting the testimony—*Maryland Casualty Co v Hill (Texas)*, 91 S W (2d) 391

Health Insurance Insanity as Constituting Sickness—Insanity, said the court of appeal of Louisiana, Orleans, constitutes sickness within the meaning of an insurance policy providing certain weekly benefits in event of sickness of the insured. In the present case the insured suffered from dementia praecox, hyperphrenic type, and was committed to an institution for the insane. She was held to be sick within the meaning of the policy but recovery of benefits was disallowed because of the fact that she was not necessarily confined to bed, a condition prescribed by the policy—*Levas v Liberty Industrial Life Ins Co (La)* 166 So 143

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Effect of Carbohydrate and Protein on Gastric Secretion.—Shay and his co workers studied five persons free of any organic gastro-intestinal disease by repeated fractional gastric analysis following meals of distilled water, a pure carbohydrate, a pure protein, and mixtures of the two. Four had a normal gastric acid response and one gave an achlorhydric response. The studies were done in order to test the validity of the claims made that mixtures of protein and carbohydrate interfere with proper gastric digestion. The gastric secretory studies included the usual titration of acidity to Töpfer's and to phenolphthalein, hydrogen ion determinations, total chlorides and quantitative pepsin. Gastric digestion was followed by quantitative determinations of reducing substances and amino nitrogen in the separate fractions. More than 6,000 determinations were made on 900 fractional specimens. It was found that mixtures of carbohydrate and protein in the test meal do not in any way interfere with gastric secretion. Not only do these mixtures not interfere with gastric digestion, but carbohydrate digestion in the stomach is prolonged and encouraged by its mixture with protein. This is probably brought about by the more favorable reaction for continued ptyalin activity in the stomach as a result of the acid combining power of the protein. The same would be true following any regurgitation of pancreatic amylase from the duodenum.

Effect of Acetylsalicylic Acid on Gastric Activity.—Schnedorf and his collaborators found that in some normal human subjects and in normal dogs single oral doses (from 1 to 2 Gm) of acetylsalicylic acid caused gastric retention, the addition of calcium gluconate tended to increase the degree of retention, while the addition of sodium bicarbonate increased the rate of gastric evacuation. Single oral doses of acetylsalicylic acid increased the total titrable acidity of the contents of the stomach, the addition of calcium gluconate diminished the rise in the acidity, while the addition of sodium bicarbonate decreased the acidity of the contents below that of the controls. In dogs with pouches of the entire stomach, the local application of acetylsalicylic acid caused a definite increase in the neutral chloride or diluting secretion of the stomach, the addition of calcium gluconate resulted in only a slight increase in the diluting secretion, while the addition of sodium bicarbonate to the acetylsalicylic acid also resulted in only a slight increase

in the diluting secretion. None of the solutions increased the formation of hydrochloric acid significantly. Prolonged daily administration of acetylsalicylic acid to normal dogs and to dogs with Pavlov stomach pouches resulted in definite augmentation of gastric secretion. With the addition of calcium gluconate the increase was not nearly so marked, while sodium bicarbonate and acetylsalicylic acid actually caused a decrease in the gastric secretion below the control values. The neutralizing and "inhibiting" actions of sodium bicarbonate and calcium gluconate on the titrable acidity of the gastric contents and on the output of hydrochloric acid may play a definite part in the ameliorating effects of these substances on the degree of gastric irritation and the incidence of ulceration produced by the prolonged oral administration of acetylsalicylic acid to dogs. Whereas the protective action of sodium bicarbonate may be adequately explained by a reduction of acid irritation, this is not true of calcium gluconate, the protective action of which against digestive disturbances appears to be due also in part to some systemic action of calcium. From the evidence available it would appear that, to obtain optimal protection when giving salicylates in large doses, the salicylates should be administered with sodium bicarbonate and calcium gluconate.

Diagnosis of Congenital Syphilis.—It is clear to Faber and Black that the quantitative Wassermann test gives an earlier clue to the absence of syphilitic infection than does the ordinary simple qualitative test. In seven of the eight presumptively nonsyphilitic babies the reaction to the initial routine Wassermann test was plus 3, but with the exception of that in one case the initial titer was low, giving an immediate indication that actual syphilis might not be present. This infant, with the initial high titer, may have been subjected to treatment had not the test on the seventh day shown a sharp reduction of the number of units of reagin to half the original figure. The progressive but very gradual decline was striking. When determined by the ordinary method, the Wassermann reaction remained plus 3 as late as the fifty-second day and was still plus 2 minus on the seventy-third. In other words, the clue of eventual negativity was given by the quantitative method on the seventh day and not until the seventy-third by the routine method. Complete and final proof that some or all of these infants may not still harbor syphilis in latent form has not been offered. They are serologically and clinically normal but must continue under periodic observation. The authors feel justified in withholding treatment in these and similar cases, first because no criterion remains for judging either the necessity of treatment or its results and secondly because arsphenamine therapy has serious risks, to which a nonsyphilitic person should not be subjected. These risks are greater than those of failing to treat a possibly but improbably present latent infection. They propose that the transmission of syphilitic reagin from mother to fetus without the transmission of syphilis itself is a soundly established phenomenon and one of sufficiently fundamental

importance to be designated by the name of its discoverer, Fildes. It is suggested that it be worded as follows: Syphilitic reagin in the blood of the new-born infant is diagnostic not of syphilis in the infant but of syphilis in the mother."

Thrombosis of Lateral Sinus and Jugular Bulb—Karelitz has observed two children in whom he believed that the source of sinus thrombophlebitis was not an otitic infection. In one case the condition was due to the spreading of a thrombus from the left lateral sinus to the healthy right side, and in the other two it was retrograde, from thrombophlebitis of the internal jugular vein. In each instance a peculiar engorgement of the tympanum was observed on the same side as that on which the sinus thrombosis was demonstrated at operation. He believes that in each instance the thrombophlebitis preceded the otitic manifestation, and he therefore wishes to present this picture of otitic congestion as a new sign of a new clinical condition, namely, retrograde sinus thrombophlebitis, which he thinks has heretofore been observed only at postmortem examination.

*Blood Transfusion in Typhoid Fever. P. T. Lantin and F. S. Guerrero, Manila. P. I.—p. 850.

"Gordon Test" for Hodgkin's Disease—Goldstein declares that seven of nine lymphogranulomatous nodes, when inoculated intracerebrally into rabbits, produced an encephalitic syndrome. In two instances, in which tissue was obtained from histologically established cases of Hodgkin's disease, this reaction was not obtained. From both, biopsy specimens were obtained on two occasions, and enough material was available at necropsy to permit making an adequate number of rabbit tests. Dosage and time of icebox storage of the suspensions varied, but all the inoculated animals remained free from abnormal neurologic manifestations. Of the control group of twenty lymph nodes five were tuberculous and two came from patients with infectious mononucleosis. None of the control glands produced signs of encephalitis on inoculation into rabbits. The study suggests that the Gordon test may be of distinct value in the diagnosis of Hodgkin's disease, especially in instances in which the histologic observations are uncertain. A negative test at the present time has no diagnostic significance. It is apparent however that to settle the question of possible "false positive tests" additional cases must be studied.

Blood Transfusion in Typhoid—Lantin and Guerrero treated forty-one severe cases of typhoid with blood transfusion and thirty-four cases without. They succeeded in reducing the fatality from 47.05 per cent in the control cases to 24.39 per cent in the cases in which transfusion was performed. They remove 150 cc. of blood from the patient and immediately replace it by direct transfusion of 200 cc. of blood from a donor. They have repeated the blood exchange the day following or as often and as many times as required by the severity of the case after an interval of from two to four days. Sometimes they gave as many as seven transfusions. In cases in which there was an initial hemorrhage they did not remove blood from the patient but proceeded at once to transfuse 200 cc. of blood from the donor. In case of initial hemorrhage in itself is a natural

method of exsanguination. They base the rationale of the method of treatment on the principle of detoxication brought about by the withdrawal of blood from the patient and its immediate replacement with new blood from a donor. They believe that this procedure brings about a more rapid detoxication and an early neutralization of the poisons in the system, an immediate introduction of protective elements and the stimulation of the defenses of the body.

- Uterine Bleeding of Functional Origin**—Wilson and Kurzrok consider five types of functional bleeding: puberty maturity, preclimacteric, ovulation, cyclic or anovulatory. Selected cases of functional bleeding are presented and they show that 1. Functional uterine bleeding is completely independent of the type of endometrium. 2. Cystic and glandular hyperplasia of the endometrium persists long after the bleeding has stopped. 3. The cause of functional bleeding must be sought for in some extra-endometrial factor. A theory to explain both menstrual and functional bleeding based on the assumed presence of a bleeding factor (or hormone) in the anterior pituitary gland is suggested on the following hypothesis: 1. Bleeding alone is due to a special hormone elaborated by the anterior lobe of the hypophysis. 2. The bleeding hormone is separate and distinct from the follicle stimulating and luteinizing hormones. 3. It is not gonadotropic but acts directly on the endometrium. 4. Its production is stimulated by the follicular hormone. 5. Its activity is inhibited but not destroyed by progesterin. 6. The actual onset of bleeding occurs when a certain concentration of the bleeding hormone has been reached and provided its action is not inhibited by the corpus luteum hormone. 7. The bleeding stops when the bleeding hormone is exhausted.
- Acute Toxic Hypertensive Syndrome of Pregnancy**—Mussey carried out ophthalmoscopic examination of the retina of 103 patients who presented the acute toxic vascular changes.

tensive) syndrome of pregnancy In 72 per cent of the cases in which the systolic blood pressure was 140 mm of mercury or more, positive evidence was found of more or less change in the retinal arterioles or in the retina proper As a rule, changes in the retina, which at first consisted of spastic narrowing of the retinal arterioles, showed a definite increase in degree and severity, with increase in the height of the systolic blood pressure and the duration of the toxemia Information obtained by retinal examination of patients who present acute hypertensive toxemia of pregnancy is a distinct aid in determining if and when pregnancy should be terminated It seems evident that when the spastic condition of the retinal arterioles is maintained, the first appearance of cotton-wool exudates and hemorrhages in the retina indicates the danger of permanent systemic arteriolar injury, in the presence of such retinal changes, pregnancy should be terminated promptly

Blood Loss During Normal Menstruation.—Barer and Fowler determined the menstrual blood loss in 100 normal women whose ages ranged from 15 to 43 years For the most part the subjects were members of the hospital staff who were in good health and whose menses were considered to be normal Cellulo-cotton pads were utilized in the collection of the menstrual flow except for five individuals who employed vaginal cups The iron content of the menstrual flow in the 100 women varied from 2.28 to 78.96 mg, which represents from 0.680 to 23.57 Gm of hemoglobin When these values are translated to terms of cubic centimeters of blood having a hemoglobin content equivalent to that of the particular individual's intravascular blood, they represent a loss of from 6.55 to 178.69 cc The mean loss for the entire group was 50.55 cc., with a standard deviation of 25.73 cc. While the greater number of cases actually fell in the 20 to 30 cc. group 50 per cent of the subjects lost between 23.21 and 68.43 cc There was no correlation between the age of the individual and the amount of blood lost There was, however, a difference between the blood loss in the unmarried (seventy-six cases, mean loss 52.96 cc.) and the married women (twenty-four cases, mean loss 42.91 cc.) The flow was more profuse in the parous than in the nulliparous subjects There was no correlation between the blood loss and the blood hemoglobin in the subjects studied As the duration of the period increases the average blood loss increases, but there are marked variations While the menstrual loss has been reduced to terms of cubic centimeters of blood to give a more graphic description of the results, it is not the volume itself but the hemoglobin and iron content of the menstrual flow which is of vital importance The loss of 2.28 mg of iron per period would require a daily iron storage of 0.08 mg to replace this loss alone The results of iron balance studies, which are to be reported later, indicate that the latter amount is far greater than the average daily iron retention and may be attained only by the administration of iron in addition to that obtained from the diet This continuous excessive iron loss may account for certain cases of hypochromic anemia which have been considered idiopathic in origin While this may not be the only etiologic factor in all such cases, it undoubtedly plays an important and frequently an unrecognized part

Cutaneous Hemorrhage During Puerperium with Development of Acute Yellow Atrophy.—Stone and Bunim report a case in which a primipara, aged 27, after a normal pregnancy and forceps delivery developed a purpuric eruption of peculiar distribution Several weeks following complete recovery from this condition she developed acute yellow atrophy of the liver and died The patient was tested for ergot but showed no hypersensitivity to it Her past history of having taken castor oil as well as quinine on a number of previous occasions without untoward reactions excludes these drugs as possible antigens Sensitivity to acacia has been reported both in experimental animals and in man Unfortunately the patient was not tested with this antigen However, following the appearance of purpura the patient was again given 300 cc. of acacia intravenously and no reaction followed The question of the relationship if any between acute yellow atrophy and the purpura or the preceding pregnancy remains The authors hesitate to consider the acute yellow atrophy a complication of the patient's pregnancy because more than five weeks elapsed between delivery and manifestations of her final illness, because

during this intervening period there was an interval of perfect health and because sections of the liver showed no evidence of any regenerative processes For the same reasons they hesitate to link the purpuric eruption with the later development of severe liver disorder

Presacral Sympathectomy for Dysmenorrhea.—Through resection of the presacral (hypogastric) nerve for the relief of dysmenorrhea and pelvic pain Black obtained excellent results in the majority of the twenty-seven cases that he cites There were nine cases of the essential and eighteen of the acquired type of dysmenorrhea Fifteen patients suffered from bladder disturbances (dysuria was severe in some and milder in character in others) There was definite pathologic change in ten cases In fourteen retrodisplacements were corrected and appendectomy and sympathectomy were performed Three had a diagnostic dilation and curettage and two a cauterization of the cervix, besides the sympathectomy Postoperative catheterization was necessary in thirteen cases Seven patients in this group had postoperative bleeding in two or three days (without pain in six, slight in one) Three had a single nerve, one a double nerve and the remainder a plexiform arrangement Excellent results were obtained in twenty-one cases A marked improvement was obtained in five cases One patient could not be located Dysmenorrhea was relieved practically 100 per cent.

Bladder symptoms were relieved immediately, but after a few months some complained of a burning on urination. This could be due to a recent gonorrheal infection, although one must consider the nerve supply to the urethra as a possible cause of continued complaint. Constipation was not relieved in a number of instances, however, in some it was corrected. The sympathetic nerve supply is so variable that failure to relieve constipation can be ascribed to this cause in some cases. Metrorrhagia was relieved in two cases. Presacral sympathectomy in addition to removing the pelvic pathologic changes in suitable cases of pelvic pain has increased the percentage of cures.

Aneurysm of Right Subclavian Artery and Innominate Vein—Cohn discusses the case of a young man who had an arteriovenous aneurysm involving the first portion of the subclavian and possibly the innominate vein. He was tolerating well the existing aneurysm as evidenced by the following facts: the patient was stabbed in the right side of the neck eighteen months prior to admission (for external hemorrhoids), he had no symptoms indicative of general circulatory disturbance, the electrocardiographic observations were reported negative and the roentgen examination of the chest indicated no marked cardiac enlargement. There was, however, evidence of pulmonary disease, but tubercle bacilli were not found on repeated examinations prior to operation. There was evidence of an established collateral circulation, as the radial pulse was good and there was no muscular atrophy. The Branham bradycardiac phenomenon was not found on several occasions. The heart was only slightly enlarged, but the existing enlargement diminished following operation. Postoperatively the radial and brachial pulses have failed to return. In spite of this, the collateral circulation has been adequate to prevent evidence of atrophy or circulatory disturbance. The value of passive vascular exercise as an adjunct in developing collateral circulation is demonstrated by the good result. The operation consisted of ligation of the internal jugular vein, ligation of the right subclavian artery and the innominate vein on each side of the fistula and obliterative suture of the vein and artery at the site of the fistula. Cure of the aneurysm resulted. The arteriovenous fistula between the right subclavian artery and the innominate vein as existed in this case is evidently unique.

Pustular Psoriasis—Although Barber seemingly gave a convincing clear-cut differential diagnosis between acrodermatitis continua and pustular psoriasis, Ellis believes that occasionally a condition is seen which defies differentiation. A case of psoriasis is reported in which the condition was complicated by a unilateral superficial pustular eruption

after severe frost bite of the hand. The eruption had features which Barber considered characteristic of acrodermatitis continua. From the literature and the case reported, one must conclude either that acrodermatitis continua is a form of pustular psoriasis or that the patient had had acrodermatitis continua for ten years and psoriasis developed later.

Sphaceloderma—Sachs describes a case of extensive ulceration, of spontaneous origin, in a girl, aged 10 years, showing no symptoms at any time. Laboratory investigation proved of little value, and the condition resisted all types of treatment. It started without any known cause and terminated after four years without apparent cause. The patient's general condition remained good throughout four years of observation. The osteomyelitis of the left humerus became progressively worse, the area was operated on and the necrotic granulations were curetted. She responded well to this, and the condition gradually improved. The wound remained more or less stationary for two years, with the occasional appearance of healthy granulations at several points. The wound has slowly but progressively improved, until at the time of writing the entire area has undergone epidermization. At no time before or during the healing was any special treatment used. The osteomyelitis is completely healed. She has no subjective symptoms and other than impairment in motion, experiences no discomfort. There remains only a little motion in the left arm, owing to adhesions to the chest wall. The left breast is gone. On lateral view there is a marked concavity of the left side of the chest, causing considerable deformity of the thorax. The scar extends across the whole wall of the chest, the upper margin reaching to the top of the sternum in the center and on the sides extending over the shoulders, the lower border reaches to the bottom of the chest wall. The scar extends down over the upper third of the right arm, on the left side it extends around the back, in the upper part to within 2 inches (5 cm.) of the spine and in the lower part to the lower pole of the scapula. Almost the entire left arm is covered by scar tissue. The edges of the scar are irregular, in places white smooth and at the same level with the surrounding skin and in places raised, well defined and red. The surface is in part smooth except for a few cordlike red bands traversing it in different directions. In the region of the left shoulder and left arm the surface is very irregular, with large masses protruding. There are large fibrous bands connecting the left side of the chest wall and the upper half of the left arm. In part the scar is smooth, stretched thin and glossy, in part it is wrinkled dull and unlike cigaret paper in appearance. Over the lateral surface of the left arm is a deep scar, at which point the incision was made because of the osteomyelitis. The history, course and laboratory observations rule out extensive ulcerations caused by tuberculosis, syphilis, actinomycosis, blastomycosis, trichosis and coccidioidal granuloma. There was no history of the ingestion of drugs, especially iodides, before admission to the hospital. The wound healed, even though the patient was taking iodides. Antimony and potassium tartrate was given to the patient as a therapeutic test, with no results. The condition does not fit in with any of the types of gangrene described.

Acne and Carbohydrates—Crawford and Swartz hospitalized ten patients with severe pustular acne who were given routine examinations, including the usual laboratory studies and dextrose tolerance tests, and the blood sugar content was again checked on dismissal. All the patients showed values for the blood sugar content in the lower range of normal at all times and gave normal reactions to dextrose tolerance tests. They were placed on a high intake of carbohydrates and were given daily intravenous injections of dextrose for two weeks. Half of the patients exhibited definite improvement. 25 per cent showed a slight improvement and none were worse. Maintenance of this diet over periods up to one year has resulted in continued improvement in 50 per cent of the patients. These results are routine local measures as the only adjuvant. These results definitely intimate that a high carbohydrate regimen is inimical to the welfare of patients with acne. It is possible that other types of foods or perhaps specific foods also may be incriminated as factors in cases of acne, but the high carbohydrate

Obesity Associated with Carcinoma of Adrenal—Graef and his associates believe that their case and the one reported by Mathias are the only ones recorded in which tumors have been found in the adrenal cortex and the anterior lobe of the pituitary gland of the same patient. Their patient, a girl 19 years of age, presented hirsutism, hypertension, obesity and atrophic striae in life and at necropsy was observed to have a metastasizing carcinoma of the adrenal cortex and an indeterminate miliary adenoma of the anterior lobe of the pituitary gland. Selective degenerative changes were noted in the nuclei of the beta cells of the anterior part of the hypophysis. Although data are not conclusive, evidence is given which tends to show that the pituitary adenoma is not merely a coincidental observation. Marked overexcretion of estrogenic substance in the urine was noted during life, and this is discussed with relation to the atresia and atrophy of the ovaries and endometrium. Clinical manifestations or pathologic evidence of changes in the pituitary gland in similar cases of metastasizing adrenal neoplasm have been found to coexist in (1) the case of a 24 year old man who had hypertension due to a tumor of the adrenal cortex and who had an acromegalic appearance (Oppenheimer and Fishberg), (2) a case of metastasizing carcinoma of the adrenal cortex in a man aged 45 in whom an acromegalic appearance developed while he was under observation during the last six months of life (Long and Gray) and (3) the 18 year old girl who had hypertrichosis with a well marked beard from the age of 3 years and at the age of 18 died of a metastasizing neoplasm of the adrenal cortex (Mathias).

Discoloration of Skin Following Use of Bismuth.—Recently Lueth and his associates observed a patient with a deep blue discoloration of the skin and mucous membranes who complained of severe diarrhea. At first the condition was considered to be argyria, but when the patient was questioned the possibility of bismuth poisoning appeared. A number of years before the patient had been told that he had a peptic ulcer. He thought the medicine given at that time was silver nitrate. Later diarrhea appeared. It had persisted for eighteen years, during which time he had ingested large amounts of bismuth salts. Histologic and chemical studies of the skin definitely excluded silver and established bismuth as the cause of the pigmentation. The term 'bismuthia' is suggested for the condition. A rough though inaccurate estimate of the amount of bismuth in the skin of the entire body was made by means of the Du Bois table for surface area. The skin used for the biopsy was taken from one of the lightest areas on the basis of its analysis about 82 mg of bismuth was calculated to have been present in the entire skin.

Differential Platelet Count.—The preserving fluid that Olef employed for both total and differential platelet counting consisted of 1 Gm of sodium metaphosphate, 0.5 Gm of sodium chloride, 0.1 Gm of dextrose and 100 Gm of distilled water.

Under optimal conditions the platelets in this solution, when observed with the oil immersion lens, appear as free-floating, isolated, clear, highly refractile bodies with numerous spinelike processes projecting from the periphery. The technic for the enumeration of the platelets is as follows. The palmar surface of the finger tip is punctured with an automatic lancet. The first drop or two of blood is discarded. A drop of the diluting fluid is then placed over the puncture wound before the blood reaches the surface of the skin, and the hand is quickly turned over so that the palmar surface is directed downward. After a sufficiently large drop of blood has escaped into the drop of diluent the mixture is applied to the surface of a small quantity (3 or 4 drops) of diluting fluid contained in a paraffin cup. The mixture is stirred gently and then transferred by means of a paraffin-coated applicator to a glass slide, usually three preparations can be obtained, as the quantity of fluid in the cup yields 3 large drops. A coverslip is placed over each drop and after the preparations have been allowed to stand for from ten to fifteen minutes a relative thrombocyte-erythrocyte count is made, the oil immersion lens being used. Sealing the edges of the preparations with liquid petrolatum will prevent air currents in them. An erythrocyte count is then done in the usual manner, and the absolute number of platelets per cubic millimeter is determined. With this method the average number of platelets per cubic millimeter in normal adults is about 500,000. The platelets as observed in wet preparations vary considerably in size. They can generally be divided into four distinct groups: group 1, about 1.8 microns, group 2, about 2.5 microns, group 3, about 3.6 microns, and group 4, consisting of irregular-shaped platelets. The behavior of the total and differential platelet counts in a number of important clinical conditions is presented and the significance of the deviations from the normal discussed. In conditions associated with thrombocytosis and at times in those associated with thrombopenia, the deviation from the normal in the differential platelet formula is usually due to an absolute or relative increase in the number of small platelets. The presence of increased numbers of the larger types of platelets is often associated with intense regenerative activity, abnormal function or hypoplasia of the megakaryocytes in the bone marrow. Normally functioning platelets are usually normal morphologically. Functionally, the smaller platelets are much more active than the larger types. The small juvenile platelets possess high agglutinating powers, and their presence in large numbers constitutes a significant factor in the causation of spontaneous thrombosis in conditions associated with thrombocytosis.

Hyperplastic Disturbance of Connective Tissues.—In summing up the salient features of the multiple lesions in his case, Roy finds that they present a hyperplastic and degenera-

tive disturbance of certain connective tissues—bones, periosteum of the long bones, skin and subcutaneous tissues of the face and extremities of the limbs, and, above all, of the tarsus of the eyelids. This observation allows him to describe a disease having for its manifestations a hypertrophy of the eyelids, of the integuments of the face and of the extremities of the limbs, and also of the bony system in general, caused most probably by an endocrine disturbance. Though appearing like acromegaly, this syndrome does not present any of the essential features of this disease. He is of the opinion that it is impossible to classify the syndrome of this patient in the category of any disorder described heretofore, whether osseous, cutaneous or palpebral. Consequently, he advances a hypothesis in regard to the etiology, a hypothesis based on endocrinologic knowledge and on certain morbid factors concerning the relations of the patient and the place of his birth. The patient belongs to a goitrous family, he was born and brought up in a locality in which hypertrophy of the thyroid is endemic. The hypertrophy of the palpebral tarsus, the integuments of the face and extremities of the limbs as well as the hyperplastic fibrous osteoperiostosis should be attributed to an upset of endocrine function in direct relation with a hereditary vice transmitted by goitrous parents or acquired as a result of a local pathologic factor which maintained a hypertrophy probably associated with thyroid derivation. The author places in the forefront of this imbalance certain physiologic disorders of the thyroid and parathyroids. The nonprogressive character of the syndrome in his patient leads him to conclude that the disorder completed its course long ago. So far as the hypertrophy of the eyelids and integuments of the face is concerned, it is easy to come to the conclusion, on consideration of a photograph taken eight years after the first one, that the small difference observed in these two pictures is due to the progress of age rather than to the continuation of the pathologic process. So far as the hypertrophy of the palpebral tarsus is concerned, perhaps one should not totally ignore the ocular irritation produced by smoke, when the patient was 20 years old, an irritation which in the space of about two months necessarily resulted in a chronic conjunctivitis. The palpebral troubles made their appearance in the fall of the same year. This inflammation, in its turn, has perhaps participated in the development of such a strange disease of the tarsus, because the endocrine or humoral predisposition of the patient was of a nature to favor the reaction of fibrous hyperplasia.

Changes in Blood Associated with Hepatic Damage.—Shumacker and Wintrobe describe the blood changes in mice and rabbits in which acute and chronic hepatic damage was produced by the administration of carbon tetrachloride. Polycythemia developed following the initial doses of carbon tetrachloride or after the dosage was abruptly and substantially increased. Refractive index determinations suggested that hemoconcentration may have played a part in the causation of the polycythemia. Occasionally the refractive index before polycythemia developed rose to values found during polycythemia. More conclusive as suggesting hemoconcentration is the increase in total plasma solids from 0.0761 to 0.0825 Gm. per cubic centimeter of plasma, which occurred in one dog during the period of polycythemia. In the rabbits similar polycythemia was observed. After injury to the liver was caused repeatedly and a chronic condition closely resembling cirrhosis was produced, anemia developed. This was usually normocytic in type, but in instances in which the liver damage was very severe and of long duration, macrocytic anemia occurred. In such instances the bone marrow was hyperplastic and macroblastic in type. It is suggested that the anemia may be the indirect result of liver damage and that the macrocytic anemia developed as the consequence of a fault in the internal metabolism of antranemic principle.

Kahn and Wassermann Reactions and Meteorological Changes.—Kelley and Short declare that the extreme variations in serologic reactions for syphilis reported by Hensley and Peter and their wide divergences between the results of Kahn and Wassermann tests on identical specimens are contrary to their own and to common experience. That the

logical changes could account for such inconsistencies is not supported by the results of their study. Repetitions were in the majority of instances highly consistent with the original tests. If meteorological variations are such an important factor as Hoverson and Petersen assert, supporting evidence should not be difficult to find in the vast literature that has accumulated on the subject of Wassermann and Kahn reactions. Hoverson and Petersen should look elsewhere for a satisfactory explanation of their results.

Sodium Citrate Spirocheticide—While preparing for darkfield examination a rather thick cover glass specimen from a laryngeal lesion of Vincent's angina, containing many pus cells and a bacterial flora consisting mainly of myriads of Vincent's organisms, Leadingham observed that the addition of a drop of a 2 per cent solution of sodium citrate caused immediate cessation of movement of the spirochetes and apparently eventual dissolution. Repeated examinations gave the same results. Later the same solution was applied to the surface of the ulcer from which the specimen had been taken. Ten minutes later no Vincent's organisms were found. None were present the next day or the day following, when the patient was dismissed.

Negative Sputum—On the basis of a numerical comparison of various methods for the demonstration of tubercle bacilli, Pinner and Wooley show that the unqualified term 'negative sputum' is practically meaningless. Many patients whose sputum is found negative on repeated direct smears and concentrations expectorate bacilli that can be demonstrated by cultural methods and guinea-pig inoculation, by the use of laryngeal smears and gastric lavage and by appropriate methods of sputum collection. Following collapse therapy, and particularly following thoracoplasties, the roentgenologic evidence of healed cavities is often misleading and always inconclusive unless confirmed by the absence of sputum or the absence of tubercle bacilli according to the strictest tests. It is urged not to use the term 'negative sputum' without stating specifically the criteria that were used to establish the absence of tubercle bacilli.

Rib Fracture from Cough—During the last three years Oechsl has looked for rib fractures as a part of the routine interpretation of roentgenograms of the chest. Among about 2,000 admissions, twelve instances of fracture involving from one to four ribs have been observed, an incidence of 0.6 per cent. Fracture in all twelve cases was due to cough. Fracture was associated with far advanced tuberculosis in all but one patient, who had bronchial asthma and bronchitis. Induced pneumothorax was present in four instances and phrenic paralysis in one case. Three of nine unilateral fractures were associated with tuberculosis in the lung on the same side, three in the lung on the opposite side, two with bilateral tuberculosis and one with asthma. Of the three patients with fractures on both sides, two had tuberculous lesions in only one lung. Of the unilateral fractures, five were right sided and four left sided. Of the total of eighteen individual fractures experienced by the twelve patients, nine were right sided. In the light of these figures, one cannot ascribe much splinting effect to the liver. The appearance of the ribs was normal in every instance, and healing was fairly prompt, depending on the treatment afforded. There was no evidence of bone atrophy or calcium absorption. Muscular action is the determining factor in the occurrence of these fractures. A typical history is that, during a severe coughing spell, the patient notices a 'catch' or 'stabbing pain' in a sharply localized area, which he can point out accurately and which later is found to be the site of fracture. The usual signs and symptoms of fracture are elicited. Without exception, the fractures were found in a line extending from a point about 4 cm from the costochondral articulation of the fourth rib obliquely caudad and laterally to the ninth rib in the midaxilla. This location corresponds to the heavy muscular attachments of the obliquus externus abdominis, where it interdigitates with the serratus anterior. In six of the author's cases the muscles attached to the shoulder girdle and to the chest wall were tense at the same time that the abdominal muscles were in strong contraction in the expiratory phase of coughing. It seems possible that contraction or tension of the shoulder girdle muscles, particularly the serratus anterior, exerting a pull laterally and cephalad, as opposed to the simultaneous pull of the abdominal muscles mesiad and caudad, may be the determining factor in this type of fracture.

Significance of Ovarian Cysts—In an attempt to determine what proportion of ovarian tumors, particularly cysts, cause functional abnormalities as shown by changes in the menstrual cycle, Mueller studied 186 cases that had a diagnosis

involving the ovary, with or without other diagnoses. Of these, 169 were diagnosed cyst, cystic change or corpus luteum cyst, with or without associated lesions. Fourteen were malignant ovarian tumors, four pseudomucinous cysts, five carcinomas of the ovary, four papillary cystadenomas, one sarcoma, eight parovarian cysts, four dermoids, two 'multilocular' cysts, two chocolate cysts, one endometrial cyst, one fibroma and one fibrosis of the ovary. In thirty-nine cases, more than one type of cyst was mentioned or the cyst was associated with inflammatory changes in the tubes, ovaries or appendix. The ages of the patients varied from 15 to 77 years. The oldest patient had a benign ovarian cyst, while one of the 15 year old patients was operated on for a pseudomucinous cyst weighing 8,100 Gm. This patient died of a pulmonary embolus. In reviewing the histories of these patients, particular attention was paid to the menstrual cycle. 102 patients gave a history of regular, normal menses, seventeen were past the menopause and twenty-one gave a history of regular menses but stated that the flow was somewhat more profuse than normal. Thus 140 of these patients gave a history of regular menses. Only forty of the entire series gave a history of irregular menses. Of these, fourteen had a diagnosis of only 'cyst' or 'corpus luteum cyst,' without any other pelvic diagnosis. The remaining twenty-six had additional diagnoses, such as fibroids, cervical polyps, salpingitis and appendicitis. There were four tubal pregnancies included in this group. Infection, either of the fallopian tubes or of the appendix, was found in twenty patients having irregular and profuse menstrual flowing. In only fourteen cases was there no complicating factor, such as infection, fibroids or polyps. Inflammatory lesions such as salpingitis and oophoritis and appendicitis, were associated with irregularities of menstruation in more than half of the cases showing this irregularity. The present conception of the pathologic physiology underlying functional uterine bleeding is that a lack of the luteinizing hormone of the anterior pituitary exists. This allows the follicular hormone to act without the luteinizing hormone and the endometrial hyperplasia so induced results in hemorrhage. In addition to hormone therapy, stimulating doses of x-rays to the pituitary and ovary have been found beneficial in certain of the functional metrorrhagias and amenorrheas. Theoretically the old treatment of bimanual palpation and rupture of a single ovarian cyst found on pelvic examination would be good treatment if followed by other measures and if the diagnosis could be definitely established but occasionally serious error might result and malignant lesions or other complications be overlooked.

Hereditary Aspect of Pseudohypertrophic Muscular Dystrophy—Hough declares that the pedigrees of families having progressive muscular dystrophy reported in the literature show that the hereditary transmission may be as a dominant or a recessive or a sex-linked characteristic. He cites a

family history presenting six cases of the disease, one of which is uncertain. Seventy-nine known individuals are recorded. The transmission was in all cases in this family through an apparently normal female. There is increasing evidence to substantiate Barker's statement that the facioscapulohumeral or Landouzy-Déjerine type of progressive muscular dystrophy is transmitted as a dominant characteristic. As these individuals frequently live to sexual maturity, they should be warned against having offspring. The more common pseudohypertrophic or Duchenne type of progressive muscular dystrophy is apparently transmitted through the clinically normal female members of the family, exactly as is hemophilia. Perhaps this is due to the fact that individuals with this type of the disease are almost always incapacitated before sexual maturity. There is sufficient evidence to prohibit reproduction by the apparently normal females in such a family but to permit offspring to the apparently normal males. The method of inheritance may be used as a basis of sound classification as it is directly concerned with the prevention of the condition. The varying types of hereditary transmission as well as other evidence seem to prove conclusively that these cases are not all one disease entity.

*New Principle in Treatment of Perforated Peptic Ulcer Preliminary Report and Case History P. E. Spangler Portland Ore.—p. 229

Treatment of Perforated Peptic Ulcer—Spangler reports a case of perforated gastric ulcer in which the course was unusually benign. The explanation lies in the neutralization of the irritant hydrochloric acid by copious quantities of sodium bicarbonate solution ingested (twelve glasses) by the patient. This suggests the possible new principle in the treatment of perforated peptic ulcers, that is, alkaline therapy by mouth prior to operation, and intra abdominal alkaline therapy during the operation directed toward complete neutralization of the irritant hydrochloric acid. Laboratory demonstration in experimental animals of the innocuousness of sodium bicarbonate solution in the peritoneal cavity and the demonstration of the effective intraperitoneal neutralization of gastric hydrochloric acid by sodium bicarbonate solution is necessary. In the light of this experience the author would not hesitate any time in a similar case to aspirate stomach contents and wash the stomach with alkaline solution, and to allow it to remain in the stomach.

*Anemia of Deaminized Casein M I Smith and E F Stohman—p 772

Anemia of Deaminized Casein—Smith and Stohman found that deaminized casein has little if any nutritional value in the nutrition of the white rat. When fed at a level of 10 per cent, deaminized casein produces in the white rat a characteristic macrocytic megaloblastic anemia with many Howell-Jolly bodies. The inclusion of good quality protein does not prevent the pathologic process, though it mitigates the severity of the anemia. Boiling deaminized casein with alcoholic sodium hydroxide, or reprecipitation of deaminized casein from aqueous alkaline solution, destroys the anemia-producing factor to a considerable extent. The intraperitoneal injection of the alcohol soluble fraction of a hydrochloric acid hydrolysate of deaminized casein reproduced the anemia definitely enough to prove conclusively that the anemia is an intoxication and not a deficiency disease.

Potassium and Cortico-Adrenal Insufficiency—Zwemer and Truszkowski endeavored to find whether adrenal insufficiency is necessarily associated with disturbances in potassium metabolism, whether the symptoms of adrenal insufficiency can be reproduced in normal animals by raising the plasma potassium to the same extent by injection and what the mechanism is whereby the adrenal cortex regulates potassium metabolism. They believe that an important function of the adrenal cortex is the regulation of potassium metabolism and that the various known symptoms of cortico-adrenal insufficiency may be explained in terms of a disturbance of cortico-adrenal-potassium interrelations. It is further considered that the beneficial action of adrenal cortex extract in certain other pathologic conditions would suggest that the same mechanism is involved.

Calcium Metabolism and Therapy in Dermatology—Lain finds that the most gratifying effects of adequate and properly administered calcium therapy are that 1 It produces a degree of sedation and stability of the sympathetic nervous system, thereby serving to give immediate relief in most acute or chronic pruritic dermatoses 2 It limits to a striking degree exudation from either mucous or cutaneous structures, whether the irritant is due to internal or to external factors 3 Administered intravenously, after the first flush of warmth passes away it gives immediate tone to the tissues, both cutaneous and muscular There soon occurs a feeling of well being somewhat like that from a narcotic drug, without the unpleasant after-effects 4 When it is given in conjunction with viosterol and foods high in vitamin D value, with an adequate exposure to ultraviolet radiation, it promises to be of special value in other skin eruptions which have for their etiologic background disturbed calcium metabolism 5 By making this presentation, the author hopes to stimulate more interest among dermatologists for a closer cooperation between the physiologic laboratory and the clinician, whereby the establishment of calcium therapy on a rational basis with a full knowledge of its values and limitations may become a reality

New Arsenical in Treatment of Syphilis and Trypanosomiasis—As a result of examining the trypanocidal activity of a large number of arsenical products, Yorke and Murgatroyd selected sodium succinylmethylamide-*p*-arsonate for detailed therapeutic trial. In experiments on laboratory animals this compound compared favorably with tryparsamide in that it was found to be rather less toxic and of somewhat greater trypanocidal activity than the latter drug. In man it was well tolerated in weekly amounts of from 2 to 4 Gm. The usual course consisted of the administration of this amount weekly until a total quantity of from 30 to 36 Gm had been given. A number of patients had several such courses, the total quantity ranging from 66 to 141 Gm while one patient had an uninterrupted course of 69 Gm, without showing any toxic signs. Apart from occasional nausea and vomiting, the only toxic signs observed were mild arsenical dermatitis in two patients and temporary jaundice in three advanced cases of neurosyphilis after prolonged courses of the drug. Visual disturbances have not been encountered. The drug exhibited the stimulating action associated with tryparsamide and other pentavalent aromatic arsenicals. In contrast with tryparsamide, the new drug exerts a definite action in primary, secondary and tertiary syphilis. In primary syphilis it alone is inadequate since, although the lesion cleared up rapidly, secondary manifestations developed subsequently. When it was combined with bismuth the effects on primary syphilis seemed to be more permanent, and so far none of the patients treated in this way have relapsed. It has a definite action on tertiary manifestations of syphilis: the lesions disappeared completely in twenty of twenty-five cases. In early neurosyphilis and in tabes it gave satisfactory results. Of eleven patients with Nigerian sleeping sickness treated by a single course, ten became clinically normal and the other was improved. Eight of these patients had pathologic spinal fluids at the time of treatment, in three of them the fluid had become normal after the single course of treatment in two it had become considerably improved and in one pathologic changes had apparently increased, although clinically the patient had become quite normal, the other two patients, owing to their clinical improvement, did not complete the treatment. In addition, a twelfth advanced case, which had failed to react to full courses of tryparsamide and other drugs, improved remarkably after a course of the compound.

Circulatory Changes in Diseases of Nervous System.

—Lewis and Pickering state that disuse whether resulting from lesions of the motor nerves from fixation of the joints or tendons or from psychic disturbances leads to a diminished circulation through the skin of the immobilized part. After loss of sympathetic supply there is some regaining of tone by the vessels of the affected limb but the skin remains in general

warmer than the symmetrical normal skin. After complete loss of motor and sympathetic supply, as in cases of longstanding anterior poliomyelitis subjected to sympathectomy, the affected limb is in general warmer than the unaffected. Section of a mixed peripheral nerve leads first to abnormal warmth but soon to persistent coldness of the denervated skin. The change from warm to cold skin seems to correspond more with degeneration of the sensory fibers. The reduction in blood flow through the skin after section of a mixed nerve is due chiefly to loss of the posterior root fibers, partly to regaining of vascular tone after loss of sympathetic supply, and partly to muscular inactivity consequent on motor nerve loss. The possibility of organic vascular change in the digital vessels in long standing cases of peripheral nerve section is also considered. The nutritional changes in the skin, subcutaneous tissues and bones are described in a number of patients with lesions of the nervous and locomotor systems. These changes may all be explained by disuse, defects in blood flow and sensory loss, and it is unnecessary to assume in explanation any "trophic" influence of the nervous system on these structures.

Transfusing Blood from Hypertensive Patients to Anemic Subjects—Pickering declares that from 400 to 500 cc. of blood from five normal donors introduced into five anemic recipients in from six to twenty-six minutes produced rises of systolic pressure varying from 0 to 16 mm of mercury and of diastolic pressure varying from 6 to 15 mm of mercury. So small a rise in arterial pressure suggests that the introduction of this large volume of fluid was accompanied by a corresponding increase in the capacity of the circulation. The blood content of the skin vessels increased during the transfusion and the color of the face and hands deepened much more than could be accounted for by increase in the hemoglobin content of the blood. The venous pressure appeared to be raised from 2 to 4 cm by the transfusion. The results of seven transfusions in which from 350 to 600 cc. of blood from donors with hypertension was introduced in from four to nine minutes into anemic recipients, show that the changes in systolic pressure varied from a fall of 4 mm to a rise of 7 mm and of diastolic pressure from 0 to a rise of 8 mm of mercury. The changes in the color of the skin and in the neck veins were similar to those seen when blood from normal donors was used. In each of the recipients receiving blood from donors with hypertension the blood pressure was again measured after two and twenty-four hours: these pressures were a little lower (from 5 to 15 mm of mercury systolic) than immediately before the transfusion, a difference probably attributable to excitement associated with this procedure. These results suggest that the blood of patients with essential hypertension is similar to normal blood in its content of pressor and depressor substances. The observations are opposed to the idea that in so-called essential hypertension the high blood pressure is due to excess of pressor or to deficit of depressor substance in the circulating blood. They could be made consistent with the view that the high blood pressure in such patients is due to a circulating pressor substance only by supposing that this substance is destroyed rapidly in vitro or in subjects without hypertension or that the substance is inactive in relatively small dilutions. The results do not exclude the possibility that hypertension may be due to the intervention of a chemical agent which is not circulating but is fixed by the tissues. The therapeutic results of using donors with hypertension were quite satisfactory and the procedure is one that may be commended as likely to benefit both the donor and the recipient.

Spontaneous Fluctuations of Blood Pressure—Schott measured the systolic and diastolic blood pressure in the ward by the auscultatory method at intervals of from fifteen to twenty minutes during about one hour in sixty-four unselected cases admitted to Guy's Hospital for reasons other than cardiovascular disease. In twelve cases there was transient or permanent hyperpiesia, the systolic pressure being 160 mm. of mercury or more and/or the diastolic 100 mm of mercury or more, the remaining fifty-two patients had normal blood pressure. Changes in the systolic pressure up to 10 mm. of mercury occurred in twenty-one cases and in the diastolic pressure in thirty-eight cases. Changes in the diastolic pressure of not more than 5 mm were observed in only seventeen cases. In the remaining forty-three cases the systolic and diastolic changes ranged from 15 to 45 mm systolic and from 15 to 30 mm. diastolic. Maximal differences existed in the systolic and diastolic pressure in each arm. The author is unable to offer any explanation for this difference whether the blood pressure determinations were done first on the right or on the left arm was of no influence. The incidence of marked fluctuations of both systolic and diastolic pressure was comparatively high in the twelve cases of hyperpiesis. Almost every conceivable type of curve representing the changes of blood pressure during the time of observation has been found to occur in the present series of cases. The main causes which are known to produce periodic changes in blood pressure experimentally and clinically are respiratory changes, periodic changes independent of respiration and having a slower frequency and diurnal changes, and the causes of nonperiodic changes are posture, ingestion of food, changes in temperature, physical exercise and emotional factors. The most important cause for changes in pressure was observed to be the emotional factor. The great variations of both systolic and diastolic pressure emphasize the often cited but neglected fact that an isolated reading of blood pressure has only a limited value. The study of the fluctuations of blood pressure as observed under the conditions prevailing in a hospital ward seems to be a functional test of the response of blood pressure to the comparatively weak stimuli caused by unrest in such a hospital ward and by the emotional upset caused by the investigation under those conditions. Abnormally high fluctuations of blood pressure may then be interpreted in an analogous way, viz., that patients exhibiting such abnormally high fluctuations, particularly if they are young and if the fluctuations affect both systolic and diastolic pressure, should be looked on as possibly being in the prehypertensive state and should therefore be treated accordingly and watched over a period of years. Abnormally high fluctuations without any reading showing a figure actually above normal would be suggestive of the first stage of such a prehypertensive condition.

Serum Test for Diagnosis of Liver Disturbances—Ucko modified the Takata reaction for the diagnosis of disorders of the liver in the following manner. Into five clean test tubes, each of a diameter of 11 mm, containing 0.2 cc. of

serum are measured 0.1, 0.15, 0.2, 0.25 and 0.3 cc. of a 0.36 per cent solution of anhydrous sodium carbonate. After shaking, the same quantities of a 0.5 per cent solution of mercury bichloride are added. The tubes are shaken again and allowed to settle. Four different types of reaction can be observed by daylight. 1 immediately after addition of the reagents, 2, 3 and 4 after one and a half hours. Reaction 1 (+++) a thick precipitation forms in all the tubes immediately after the addition of the reagents. Reaction 2 (++) all the tubes show a uniform turbidity. Reaction 3 (+) in the first three tubes a uniform turbidity is present, the remaining two tubes are translucent. Reaction 4 three or more tubes are translucent. Of 132 patients tested by both methods, the results of the two reactions differed in twenty-six cases. 1 Of four patients with a positive modified reaction and a negative Takata reaction, three were suffering from liver disease which was confirmed in two of them at postmortem examination. In the fourth patient with a general carcinomatosis, secondary deposits in the liver were highly probable. 2 Of twenty-two cases with a negative modified reaction and a positive Takata reaction, the possibility of a liver involvement has to be admitted in three, while nineteen cases were apparently free from any liver disturbance and no probability of such a complication arose from the clinical picture. Only seven of these nineteen patients had a really positive Takata reaction, while the remaining twelve showed only flocculation in two tubes of the range. It seems therefore that the results of the Takata reaction would be more conclusive if the so-called weakly positive reaction (+) was considered negative. The comparison of the two reactions shows that the modified reaction is capable of indicating liver disturbance with more certainty than the original Takata reaction. In addition to the technical advantages, the gradation of the results of the modified reaction offers the possibility of distinguishing between different forms of liver disease.

Use of Tapioca in Immunization with Snake Venoms—Mallick studied the effect of the addition of a sterile suspension of tapioca and of aluminum hydroxide to the venom solutions employed in immunizing animals for the production of

antivenene He found that when tapioca suspensions were added it was possible to bring horses to standard titer against both cobra and daboia venoms with greatly reduced dosage of the venoms, the quantities employed being one third of that found necessary formerly. Comparative trials in goats showed that the addition of tapioca was of special value in immunization with cobra venom and that this addition was more satisfactory than the use of aluminum hydroxide. The extensive suppurative reactions with abscess formation, which occurred when tapioca was not employed and with the larger doses formerly used to reach titer, were not observed when tapioca was added or were of much less degree.

Cirrhosis of Liver Following Carbon Tetrachloride Intoxication.—Radhakrishna Rao found that the repeated administration of small doses (from 0.1 to 0.2 cc. once or twice a week) of carbon tetrachloride subcutaneously to albino rats produced toxic cirrhosis. The fibrous tissue was mainly distributed around the hepatic venous tree, which showed sclerotic changes in its larger divisions, its genesis in the cirrhosis thereby induced was traced to a disorganization, collapse, condensation and sclerosis of the perisinusoidal reticulum around the hepatic terminals, consequent on a necrosis of the parenchyma in the same area.

Anemia in Pregnancy—Boycott examined 222 unselected patients attending the antepartum clinic at University College Hospital. One hundred and seventy-two always had hemoglobin above 80 per cent, fifty hemoglobin below 80 per cent on at least one occasion and twenty-five below 70 per cent. Twenty-six cases in which the hemoglobin was below 80 per cent were examined in detail: their histories and present states gave ground for supposing that the low level of hemoglobin was due to pregnancy alone. It was found that they were equally divided into those with normal and those with subnormal color indexes. These two classes could also be distinguished on clinical and hematologic grounds. There is evidence to show that there is an inconsistent increase in the plasma volume in pregnancy causing a dilution of the red cells, and it has been suggested that the existence of the group with low hemoglobin figures and normal color indexes is explicable on this basis. On the grounds of hematologic resemblances and satisfactory response to iron treatment the group with low color indexes has been assigned to the class of anemia due to iron deficiency. The two groups are not mutually exclusive. Thirteen of these have been ascribed to iron deficiency due to the demands of the fetus in combination with either dietary insufficiency or defective utilization of iron. The remainder occurred in patients who had some complicating disease: the majority of these were of the hypochromic type. Although the series is too small to establish the preeminence of any factors as a cause of anemia in pregnancy, the evidence goes to show that diseases which cause anemia in the normal subject also predispose to anemia in pregnancy. Although the data are suggestive it is not proved that social status, age or parity affects the incidence of anemia.

Placental Extract in Modification of Measles—To shorten the time for the fractionation of globulins and to get a dry form of extract that may be better preserved, Chu and Chou used methyl alcohol as a precipitating agent, following the method of Liu and Wu. The redissolved extract is immunologically as potent as the preparation made from ammonium sulfate precipitation. The dry extract is convenient for pooling and may be stored without rapid deterioration. When the dry product is redissolved and administered intramuscularly to susceptible family contacts early in the incubation period, either modification of measles or its complete prevention may be the result. If the nonimmune children who are intimately exposed to measles at home are given the extract on the fourth or fifth day after exposure, a dose of from 0.01 to 0.025 Gm. of the protein per kilogram of body weight is adequate for the successful modification of measles.

Congenital Bone Syphilis—Jung gives an analysis of the roentgenologic changes in the long bones of sixty-two infants less than 1 year of age, including six stillborn premature fetuses. A zone of decreased density just proximal to a zone of provisional calcification (osteochondritis) was found in sixteen cases. Cases were placed under this category if the reaction was sharply outlined and if the bony trabeculation inside such an area could be seen in normal orderly arrangement, even though decreased in number. When the zone was irregular in outline and actual destruction of the bone could be seen, it was included as an osteomyelitic process. At an advanced stage of osteochondritis, a zigzag or sawtooth type of lesion in the region of the metaphysis was found in ten infants. In four of the ten cases this form of osteochondritis was the only positive sign present. When the lesion is further advanced with evident bony destruction it should be considered an osteomyelitic change. As the change progresses, epiphyseal separation may occur. The so-called epiphyseal separation was present in eleven cases, the distal ends of the radius and ulna being the most frequent location. Osteomyelitis is the most common lesion in advanced congenital bone syphilis. In the fifty-six syphilitic infants born after 1920, osteomyelitis was present in forty-four. Thirty-one showed symmetrical distribution of the lesion. Typical symmetrical punched out destruction at the upper inner aspects of the femur was found in fifteen instances. In three of them there were the only diagnostic syphilitic changes. Fairly extensive osteomyelitic changes involving the shaft of the long bones were present in five cases. There were eleven cases in which osteochondritis was present without any definite evidence of osteomyelitis. These included all the six stillborn premature fetuses and the other five cases were all in the first month of life. Periostitis without definite evidence of osteochondritis was present in five cases.

in four instances. Of the twenty-seven cases of periosteal thickening, eleven showed two or more layers of periosteal shadows with a thin zone of radiolucency between, exhibiting a tendency toward ossifying periostitis. The supportive type of periostitis was usually seen accompanying marked osteochondritis. Periostitis of this type was seen in twenty of twenty seven cases showing osteomyelitic changes.

Lipoid Nephrosis and Azotemia P. Gautier—p. 329

*Clinical Diagnosis of Strangulated Diaphragmatic Hernia L. Garot. p. 337

*So-Called Hilus Pneumonias of Children A. Carrau and H. C. Bazzano—p. 354

Diagnosis of Strangulated Diaphragmatic Hernia.—In discussing the diagnosis of strangulated diaphragmatic hernia, Garot says that the epigastric pain is intermittent and at times almost unbearable. Vomiting may be the first symptom of the occlusion or may not appear for several hours. Dyspnea is an early symptom and may be so marked as to be accompanied by the use of the accessory respiratory muscles. The intensity of the cyanosis varies. The facies is changed after the first few hours and recalls the so-called abdominal facies. The subject is in shock but has no fever. Thoracic symptoms are dominant. Dilatation of the left hemithorax with reduction or even repression of the respiratory expansion can be found by inspection and palpation. The heart is pushed toward the right. Differential diagnosis between intestinal invagination and a strangulated diaphragmatic hernia is accomplished by means of the clinical signs and symptoms and especially by x-ray examination. Strangulated diaphragmatic hernia of the stomach or the intestine constitutes an accident which carries a severe prognosis. Death may supervene after a time, varying from a few hours to two or three days. The only possible treatment is surgical, and hence the early diagnosis of this relatively rare disorder is most important.

Hilus Pneumonias of Children.—Carrau and Bazzano believe that the pneumonias which are called hilus pneumonias because of the x-ray observations are in reality in the cases observed by them pseudohilar. These pneumonias are localized in the right or left lower lobes or in the middle lobe, the latter constituting a group around the hilus during their entire evolution, while the two former localizations are hilar at the beginning but extend toward the pulmonary bases as they develop. These facts explain why this variety of pneumonia ascends. X-ray examinations, both oblique and in profile, are necessary in order to verify the exact anatomic situation of the process in relation to the hilus. Initial pneumonic bronchial adenopathy is not constantly observed. The pneumonias can begin in the pulmonary parenchyma around the hilus, but in the majority of the authors' cases the initial clinical roentgenologic point was always in the dorsal portion in the middle lobe, always near the inner lobe fissures. Consequently in the upper lobes it is below and dorsal, in the lower lobes it is above and dorsal, and in the middle lobe it is posterior and near the fissure.

Tuberculin Skin Reactions in Children.—Between 1921 and 1935, inclusive, Nobécourt and Briskas made Pirquet tests and when necessary intradermal tests on 1,989 children aged between 6 and 10 years. Of these, 58 per cent were boys and 42 per cent were girls. The percentage of positive reactions was 107 for the combined groups, and 12.7 for the boys and 8 for the girls, separately. The interpretation of these results involved considerable difficulty. Positive cutaneous reactions are obtained in children having active tuberculosis or occult tuberculosis or being carriers of discrete lesions which are not in any way active. When the positive tests were analyzed in greater detail as to sex distribution and frequency over the

fifteen year period, the conclusion was advanced that the number of children of this age group contaminated by tubercle bacilli had diminished since 1929. The number of actively tuberculous had not changed materially. In the seventh and eighth years the proportion of active tuberculosis was lower in boys than in girls. In the ninth year the proportion was raised in the boys, while it was lowered in the girls. In the tenth year the proportion diminished in both boys and girls although remaining slightly higher in the former. It was notable that between the sixth and the tenth year there was an increase in the percentage of positive cutaneous tuberculosis reactions, which contrasted with the relative fixity of the percentage of active tuberculosis.

*Protection Against Yperite (Dichlorodiethylsulfide or Mustard Gas)—Prophylactic Treatment Against Yperite A. Schraff—p. 591

Protection Against Yperite (Mustard Gas).—Schraff reports observations on the efficacy of various therapeutic and prophylactic measures that are employed against yperite (mustard gas). He was able to make these tests on a man who, to satisfy his curiosity, had burned himself with yperite and who requested that the protective measures be likewise tested on him. Twelve different patch tests were made (ten on the back and two on the upper arm). Some of the tests corroborated observations made by other investigators, for instance, that the impairment is the more severe the earlier the first sign, reddishness, appears, that is the shorter the period of latency. The tissue lesions reach their maximum after forty-eight hours and after that they commence to subside. The author differentiates three stages of impairment by yperite: (1) reddishness and swelling, (2) blister formation and (3) tissue destruction. He describes and then discusses the appearance of the various patch tests after forty-eight hours. He was able to corroborate Muntz's observation, namely, that washing with a suspension of chlorinated lime (1:10) and rinsing with water is most effective when done during the first ten minutes after exposure to mustard gas. Bandaging with a 5 per cent chlorine petrolatum (0.5:10) was likewise found helpful for prophylactic treatment. However, he observed also that the area which was washed with chlorinated lime solution fourteen minutes after exposure was considerably less impaired than the area that remained untreated. The aforementioned chlorine petrolatum did not prove effective as a protective ointment against the gas but only for prophylactic treatment, that is, after exposure to the mustard gas.

Action of Vitamins on Healing of Wounds.—Proto made experiments to ascertain the action of vitamins A, C and D on the healing of wounds in rabbits. The animals, both those treated by the vitamins and the controls, were normally fed and kept in the same condition. The animals treated by vitamins were placed in the following groups: (1) those treated by administration of the vitamins by the mouth, (2) those treated by application of the vitamins on the wound and (3) those treated simultaneously by oral administration and local application of the vitamins. The animals in each of the groups were placed in the A, C and D groups, according to the vitamins that were administered to them. The process of healing is not modified at all by vitamin C, whether administered by mouth or locally applied, but it is slightly modified by vitamins A and D given by mouth and greatly and favorably modified by local application of these vitamins to the wounds, especially vitamin A. The time of healing is greatly lessened and the condition of the wounds is much better than in the controls.

 p 829

Cavities in the Placenta—Spirito states that cavities are found in the normal human placenta some of them are true cysts of decidual or trophoblastic origin or come from colliquation of infarcts. Those of a decidual origin are located between or within the cotyledons. Placental cavities originate in necrosis and colliquation of the villi, are located within the cotyledons, and do not have the shiny white zone of delimitation that cysts and pathologic cavities may have. Histologically, the walls of placental cavities consist of more or less perfectly identifiable villi, while those of other placental formations consist of decidual or trophoblastic cells or by other cells similar to those of the villi but greatly changed like those found in infarcts. Placental cavities have no relation with fetal circulation. With the aim of differentiating the several formations of human normal placenta, it is advisable to give the name of placental cavities to those of villous origin (which were described the first time by Poso and Clemente), the name of cysts (subchorial and intraplacental, according to their location) to those of decidual, trophoblastic and infarct origin, and the name of cavitary lesions or hemorrhagic foci to the pathologic cavities.

Multiple Metastases from Chorionepithelioma—Vignali says that the presence of a greatly enlarged uterus of softened consistency, with an open cervix and expelling dark blood and remnants of tissues, similar to placenta, is an indication for immediate complete hysterectomy, with removal of the adnexa which according to the literature controls further development of metastases and modifies metastases already present. His patient, aged 20, entered the hospital three months after a normal labor and puerperium with a syndrome of cerebral hemorrhage, with left hemiplegia and hemianesthesia and also with slight fever. The condition remained stationary for three weeks without responding to symptomatic treatment, after which the fever increased and a grave syndrome of albuminuria, azotemia and blood in the feces, urine and vomiting, in addition to toxic symptoms, made its appearance. The patient began to discharge dark blood through the genitals. Genital examination showed a large tumor in the uterus. A clinical diagnosis was not made. The syndrome was caused by a chorionepithelioma of rapid evolution of the uterus with metastases to the brain, kidney and intestine. The uterus and adnexa were entirely involved in the tumoral process. The ovaries were polycystic. The metastases to the brain, kidney and intestine were extensive, with foci of hemorrhage with the blood in a process of disintegration. An extensive focus of hemorrhagic infiltration was located at the internal capsule, under the Rolandic fissure. The author states that in his case the evolution of the disease was so rapid that hysterectomy at the time of admission of the patient to the hospital, when the cerebral but not the renal and intestinal metastases had taken place, probably would have resulted in no benefit to the patient.

Vertebral Lesions in Undulant Fever—Pratesi says that the clinical diagnosis of spondylitis melitensis may be considered impossible. A positive diagnosis can be made only by the characteristics of the vertebral lesions in the roentgenogram which are characterized by moderate destruction of the bone and intense formation and reconstruction of the bone. Early in the development of spondylitis melitensis the vertebral alterations are not clear in the roentgenogram. Nevertheless the diagnosis is made by the existence of serologically proved undulant fever in the history of the patient the presence of

lumbar or lumbodorsal spondylitis of a scoliotic or kyphotic type and, in the roentgenogram, of the moderate destruction and excessive bone formation and reconstruction of the involved vertebra with absence of symptoms and roentgen signs of ossifluent abscess. The author reports a case of spondylitis melitensis in a patient, aged 46, in whom the diagnosis of Pott's disease was entirely excluded.

Parathyroid Function—Morros Sardá and his collaborators studied the modifications of the organic and inorganic phosphorus and carbohydrates of muscles of rabbits injected with parathyroid extract, creatinine or the two substances simultaneously. The authors conclude that the injection of parathyroid extract causes an increase of the total phosphorus in the muscle with a predominance of the inorganic over the organic fraction. Creatinine, when intravenously injected, brings about a slight increase of the phosphorus compounds in the muscle. The simultaneous injection of parathyroid extract and creatinine is followed by marked accumulation of phosphorus in the muscle, with predominance of phosphagen, and also by an accumulation of carbohydrates in the muscle which is at its peak one hour and a half after the injection is made. Parathyroid functions play a part in the metabolism of creatinine by favoring the esterification of the latter into phosphagens and its utilization in this form by the muscles. The antitoxic functions that the parathyroids are supposed to have depend on the intervention of the parathyroid hormone in the formation of phosphagen. Therefore the lack of esterification of creatinine would result in the presence of free creatinine and guanidine, the accumulation of which would result in the development of toxic symptoms. The absence of the parathyroid hormone would result in incomplete or difficult formation of the creatine-phosphoric acid complex, the accumulation of creatine derivatives and the development of autotoxic symptoms.

Dysgenesia of Respiratory Tract—According to Morelli there is a form of congenital subpleural giant emphysema that is one of several types of complicated syndromes known as dysgenesia of the respiratory tract (impaired intrauterine development of one or several segments of the respiratory tract). Emphysema in these cases is in direct communication with the bronchial tree and with the pulmonary alveoli at the seat of implantation of the bleb. Iodized oil intrabronchially injected fails in passing to the sac, but if a weak solution of methylene blue is injected into the sac by the transthoracic route, the dye passes immediately to the bronchi. The diagnosis is made by roentgenography of the lung which shows an irregular line of division between the lung and the emphysema. The prognosis depends on the significance of coexisting malformations. In the three cases of the author, congenital emphysema was complicated by malformations of the pulmonary artery, erythremia and paradoxical cyanosis. The anatomopathologic study of the respiratory tract performed in the three cases proved that the main malformation was in the pulmonary artery and consisted in defective development of the elastic fibers of the artery which were few and thin.

Cholesterosis of Gallbladder—In a study of 600 cholecystectomies performed during the period between 1925 and 1934, Troell found three cases of so-called lime bile and twenty-three of cholesterosis or strawberry gallbladder. Besides the stones, the gallbladders in the first group contained an amorphous, putty-like substance the color of which was like that of the stones. This "lime bile" was possibly the forerunner of the stones. Of the twenty-three cases of the cholesterosis group, nineteen presented stones. In seven of these there was present a solitary stone made up entirely, or almost entirely, of cholesterol. In two cases large cholesterol stones were associated with smaller stones. In five there were found small mulberry stones the chief component of which was cholesterol. On gross inspection these gallbladders presented a fine white or yellowish white structural network above the mucosa. It gave the impression in one of the cases of incrustated cholesterol. In two cases the reticulated mucosa showed prominent, yellowish white nodes in its entire extent. In one case formations resembling pedunculated papillomas were observed. Microscopic examination revealed chronic inflammation in eighteen and acute inflammation in three of the cases. Deposition of cholesterol was the characteristic feature. In the subepithelial connective tissue layer there were clusters of large, clear round or polygonal phagocytic cells with a small nucleus, containing fat and giving the cholesterol reaction. The source of cholesterol in strawberry gallbladder was believed by some observers to be the result of secretion by the mucous membrane, while others, notably Aschoff, held that its source was the gallbladder bile from which it was absorbed by the mucosa. By analogy with the stones of "lime bile," one is tempted to conclude that cholesterosis represents the first stage in the formation of cholesterol stones. Further observations will be necessary before this hypothesis can be accepted.

Late Results of Treatment of Gastroduodenal Ulcer and Gastric Cancer—Harms presents a follow-up study of late results of surgical therapy in 846 cases of benign lesions of the stomach and duodenum and of 432 operations performed for malignant disease of the stomach. The operations were carried out during the period between 1920 and 1927. Radical operations for gastroduodenal ulcer gave entirely satisfactory results in 80 per cent of the cases, while the indirect methods (palliative operations) gave good results in only 50 per cent. No difference was noted in the late results of the first Billroth and the second Billroth operations. Failure after gastroenterostomy and pyloric exclusion were noted with the greatest frequency in the younger patients. It was only after the fifth decade that better results were noted. Even the penetrating duodenal ulcers not amenable to resection still offered a relatively good prognosis in persons past 50. Resection of the pylorus and antrum and segmental transverse resection are likewise followed by better results in the older patients. The first Billroth operation appeared to be best suited for the younger patients. The longer the lapse of time since the operation, the better were the results with the first Billroth operation, and the worse with the indirect procedures. Better late results could be expected when the resection of the pylorus and antrum was undertaken for an extensive ulcerative lesion than when it was performed for a superficial ulcer. Peptic jejunal ulcer was the principal cause of failure after gastroenterostomies and pyloric exclusions (134 and 15 per cent, respectively). The transverse resection gave an incidence of 78 per cent of recurring ulcer and 6.1 per cent of disturbances of motility. Following the second Billroth method of resection the incidence of peptic jejunal ulcer was 0.8 per cent and that of recurring ulcer 25 per cent. The failure to obtain good

results after the first Billroth method of resection was because of recurring ulcer in 41 per cent and narrowing of the anastomosis in 34 per cent. Of the 432 cases admitted with the diagnosis of cancer of the stomach, 75 per cent were inoperable. The operative mortality was 32.9 per cent. Peritonitis was the most frequent cause of death. Most of the patients surviving the operation died within the first two years, 33½ per cent survived the five year period and 8.3 the ten year period. The best prognosis was offered by adenocarcinomas limited to the stomach with an average duration of not more than seven and a half months. Prognosis appeared to be somewhat better in the older patients.

Appendiceal Inflammatory Tumor and Abscess—In his indication for operative intervention in acute appendicitis, Suermondt is governed by the question of whether the inflammatory process manifests a tendency to encapsulation and not by the number of hours elapsed since the onset of the attack. A patient with an acute spreading peritonitis is submitted to an appendectomy regardless of the number of hours elapsed. The presence of diffuse peritonitis constitutes an even more stringent indication for operative intervention. On the other hand, a patient presenting himself with a sharply delimited inflammatory swelling in the appendiceal area even before forty-eight hours has elapsed is treated on a conservative plan. This consists of absolute rest in bed in the Fowler position, strict diet and application of an ice bag. No attempt is made to differentiate sharply between an infiltrate and an abscess. The infiltrate may undergo complete absorption in which case the appendectomy is performed six weeks later. The inflammatory swelling, on the other hand, may continue to grow in size and to give rise to pain. The danger of perforation into the free peritoneal cavity is imminent if the abscess enlarges upward or medially. Rise in temperature, onset of vomiting and muscle rigidity that did not exist before constitute together with the type of enlargement already described, an indication for immediate operative intervention. The abscess is incised and drained. No attempt is made to find or to remove the appendix. When the approach to the abscess is through the free peritoneal cavity, the latter is carefully protected with iodoform gauze, which remains undisturbed and is removed some time after the operation. An abscess pointing downward is treated conservatively in the Fowler position. It forms, as a rule an abscess of the pouch of Douglas. Such abscesses, according to the author, show no tendency to perforate into the free peritoneal cavity. They usually perforate spontaneously into the rectum, vagina or urinary bladder. The appendectomy was performed eight weeks later. To prove his contention, the author submits the statistics of the clinic in Leiden, where 2853 patients having acute appendicitis, with or without an acute spreading peritonitis, were treated in the last twenty-five years by immediate operation, with a mortality rate of 27 per cent. There were 407 cases of inflammatory swelling in which treatment was given on a conservative plan with a mortality of 0.7 per cent. Of this group, 256 patients had recovered without any intervention. In 151 the abscess was incised. There were two fatalities in this group. Of the 405 surviving patients, 324 were submitted to a later appendectomy with one fatality (0.3 per cent). Eighty-one did not return for the appendectomy because they were free from symptoms.

Hemolytic Shock—Woytek states that, despite some 350 blood transfusions performed annually in Sauerbruchs clinic, there were no fatalities and but few complications. Three cases of profound hemolytic shock were promptly saved by recourse to the method developed by E. P. Hesse and N. Filatov in 1932 and consisting of an immediate transfusion with com-

patible blood. From his observations the author concludes that the usual blood group determination with the aid of test serums does not guarantee against mishaps. Neither can absolute reliance be placed on the biologic test. The latter was negative in the three cases. Blood from a universal donor is more likely to cause reactions than that from the same group. Repeated transfusions utilizing the same donor are more likely to give rise to anaphylactic shock. The following rules were adopted in Sauerbruch's clinic: 1. Group determinations are made by testing at least twice and utilizing different serums. 2. The effect of the recipient's serum on the erythrocytes of the donor and the reverse is determined by direct cross-testing. 3. Universal donors are not used. 4. The biologic test is regarded valuable and is used as an adjunct but is not permitted to replace blood grouping. Experimental studies of E. P. Hesse and N. Filatov established that the symptoms of hemolytic shock are due to a direct toxic effect on the vessel walls of depressor substances released by the breaking down of the erythrocytes. This results in dilatation of the venous capillaries and in spasm of peripheral arterioles. The result is a fall in the blood pressure and impaired heart action because of insufficient return of venous blood to the right side of the heart. Cyanosis, dyspnea and particularly anuria are explained by the destruction of the erythrocytes with consequent lowering of the respiratory function and embolic closure of the finest pulmonary and renal vessels. The vascular phenomena of hemolytic shock resemble those of histamine shock. The red cells are the carriers of histamine. Hemolysis is the result of agglutination and breaking down of erythrocytes of the donor by the serum of the recipient. In cases in which control determinations of blood grouping were made, an error in determination was found to be the most frequent cause of hemolysis, as in one of the author's cases. In the remaining two, control tests revealed no error. The author speculates on the possibility of there existing a heretofore undiscovered incompatibility in the blood of two persons belonging to the same blood group. There may exist subgroups which are not recognized by the usual method of group testing. Failure to recognize early symptoms of hemolysis was responsible for the fatal result in most of the reported cases. The most characteristic and suggestive subjective symptom is the excruciating backache, resembling in its severity that of renal colic. According to Hesse and Filatov, it is the result of a spasm of the renal arteries. The cases reported by the author presented symptoms of severe hemolytic shock. Reinfusion with compatible blood accomplished in all three a prompt and lasting recovery. The author therefore concludes that the method proposed by Hesse and Filatov offers a prompt and efficient therapy of hemolytic shock.

Electrometric Determination of Halogen in Blood

Because their former use of the electrometric principle for the determination of small amounts of iodine in the blood was complicated, Paal and Motz have simplified their procedure. From 20 to 25 cc. of oxalated blood or several grams of tissue is placed in the closed system for incineration. After heating the quartz tube between the combustion flask and the ice-cooled absorption receiver (the first absorption receptacle contains 25 cc. of a 20 per cent solution of iodine free sodium carbonate and the second 15 cc. of a 10 per cent solution of sodium carbonate) and after adjusting the water jet pump the suction of which is throttled not only by the glass wool in the absorption receptacles but also by an interposed set screw, they suction from 100 to 115 cc. of concentrated sulfuric acid into the

distillation flask through a capillary tube with funnel attachment. While the distillation flask is carefully heated with a bunsen burner, a 30 per cent solution of hydrogen peroxide added in drops until complete decolorization has been obtained which as a rule requires about 50 cc. Then, after about 15 cc. of a 10 per cent solution of sodium sulfite has been added, distillation is continued for about twenty minutes, so that iodine which might have been formed, is again reduced to iodide. The alkaline absorption fluids are washed in a Kjeldahl flask. In order to destroy possibly existing oxidation stages of iodine, sodium sulfite (in an amount that can be placed on the point of a knife) is added and dissolved. Then, in order to precipitate the iodine in the fluid, a mixture of 50 cc. of two normal sulphuric acid and 1 cc. of tenth normal silver nitrate is added. The weakly acidified solution becomes at once turbid with halogen silver precipitates (all iodine as silver iodide, bromine as silver bromide and a little chlorine as silver chloride). Precipitation is promoted by adding a few drops of dilute nitric acid and by a short boiling. After several hours of standing, the precipitate is filtered through a porcelain filter that has been boiled with nitric acid and has been washed with halogen free and then is thoroughly washed several times with several cubic centimeters of hot, iodine free water. The silver precipitate is decomposed in the dish by the addition of a hot mixture of 1 cc. of a 10 per cent solution of sodium hydroxide with 1 drop of hydrazine and from 2 to 3 cc. of bidistilled water. In the course of the reduction, metallic silver is formed and held back on the filter, whereas the halogens pass into the filtrate. The filter residue is thoroughly washed with small portions of hot iodine free water, so that the entire quantity of filtrate is at the most 12 cc. After the filtrate has been acidified with about 4 cc. of normal sulfuric acid, the electrometric test is made. The authors give a table of report of the electrometric determination of the blood iodine and discuss the electrometric determination of chlorine and bromine.

Short Wave Therapy in Hiccups—Weissberg points out that hiccups may develop in the course of encephalic processes, influenza, abdominal disorders and after laparotomy. The author says that hiccups usually yield rapidly to treatment with short waves. He describes six cases in which the hiccups had persisted for from several hours to two weeks and in five of which the hiccups were counteracted by weak doses of short waves applied to the occiput, the epigastric region or the cervical sympathetic. He thinks that, although the mechanism of the treatment is not fully explained, the possibility of the removal of a symptom that greatly impairs the general condition justifies a trial with short wave therapy in cases of persistent hiccups.

Leukorrhea and Exudative Diathesis—In a discussion of gonorrhea Geiger points out that the opinion prevails that endogenic factors are active before exogenic factors (trauma of pathogenic bacteria trauma) exert their influence. He states that the role of trichomonas infection has been over-

and that constitutional factors play a part in nongonorrheal leukorrhea. He shows that constitutional anomalies such as infantilism, asthenia and the exudative diathesis are closely related to nonspecific leukorrhea. He points out that the term "exudative diathesis" designates a predisposition to an increased secretory action of the skin and of the mucous membranes during childhood and that a variety of disorders of the skin and of the mucous membranes, such as urticaria, impetigo, strophulus, chronic catarrhs of the respiratory tract and nongonorrheal vulvovaginitis, are frequent in such cases. Neuropathic conditions often appear as accompanying symptoms. The author observed that in many patients with frequent catarrhal disturbances of the respiratory apparatus the anamnesis revealed an exudative diathesis during childhood and that many of the women and girls received treatment also for nongonorrheal leukorrhea. At the women's clinic later, whenever the anamnesis of women with nongonorrheal leukorrhea disclosed exudative processes during childhood, the nasopharyngeal region was carefully inspected and nervous symptoms (urticaria, bronchial asthma, angioneurotic edema and vasomotor rhinitis) were found in nearly all these cases. In treatment he largely dispensed with the local therapy of leukorrhea and stressed a general treatment in the form of a predominantly vegetarian diet with restricted salt intake but with a high vitamin content. He also prescribed cod liver oil and calcium. Usually this treatment produced improvement after from ten to fourteen days. There was improvement in the leukorrhea and in the general condition, and the accompanying symptoms, such as rhinitis, disappeared. When the treatment was discontinued, relapses occurred.

Benign Spontaneous Pneumothorax of Tuberculous Origin. P Heilmann—p 824

Modified Ziehl-Neelsen Staining Method—Lange describes a modification of the Ziehl-Neelsen method. The air-dried, relatively thick smear is left for twenty-four hours in carbolfuchsin that has been diluted to half the concentration by means of 5 per cent phenol. After rinsing with water, it is rapidly decolorized with 3 per cent hydrochloric acid alcohol, and it is left in 96 per cent alcohol until decolorization has become complete. Then the preparation is placed for four or five minutes in aqueous solution of iodine and dried with blotting paper. Instead of treating the specimen with aqueous solution of iodine, it is permissible to pass over the decolorized and dried (with blotting paper) preparation some cotton that has been saturated with tincture of iodine. The author maintains that this method of staining reveals a much larger number of tubercle bacilli than does the customary Ziehl-Neelsen method, and for this reason it is possible to dispense with the methods that are employed to bring about an abundant growth of tubercle bacilli. Moreover, this modification is less expensive and less complicated. It is especially suited for the demonstration of tubercle bacilli in the sputum but not for their detection in the feces.

Experimentally Produced Reflex Epilepsy—Baumann points out that formerly it was assumed that in entirely normal subjects epileptic attacks could be elicited by pressure on a sensory peripheral nerve and centripetal conduction to the brain. This standpoint is no longer tenable in that it is now believed that a convulsive tendency in the central nervous system is necessary. This convulsive tendency may be congenital (as in subjects with genuine epilepsy) or acquired by cerebral trauma,cretory disturbances or brain lesions. In this con-

nection the question arises whether so-called reflex epilepsy may develop in patients with a convulsive tendency. The author thinks that in the present status of our knowledge the answer must be affirmative. The type of the eliciting agent is of no importance, at any rate it is erroneous to assume that only a pressure from a scar or from a tumor could elicit an attack of reflex epilepsy. Theoretically considered, every stimulus, whether mechanical, thermic, chemical or electrical, can do this. In discussing the conduction of the stimulus from the periphery to the central organ, the author points out that it is not likely that it takes place by way of the sensory nerves, he believes with Foerster that it occurs by way of the vascular sympathetic. This theory is corroborated by experiments, which the author carried out in collaboration with Muck, who, in the course of his epinephrine probe test, had found that after freezing of a radial artery with ethyl chloride the white streak sign appeared on the same side of the nose and in cases in which the phenomenon had not been present before. When the epinephrine probe test was once made on a patient with suppurating meningitis, the freezing was followed by an epileptic attack, although the patient had never before had such an attack, that is, the attack was elicited by way of the vascular sympathetic. Subsequently, Muck made his epinephrine probe test on a number of patients with genuine and with symptomatic epilepsy, many of whom were patients in the author's clinic. The author describes his observations on five patients, which show that by spraying with ethyl chloride true epileptic attacks can be elicited in persons with a convulsive tendency, the majority of whom belong to the group of patients with traumatic or symptomatic epilepsy. To be sure, reflex epilepsy by means of freezing with ethyl chloride can be elicited also in some cases of genuine epilepsy, but the author gained the impression that it is more readily elicitable in traumatic and symptomatic than in genuine epilepsy.

Osteogenesis Imperfecta—Winkelmann describes studies on the pathologic anatomy of osteogenesis imperfecta on the basis of which he reaches the conclusion that it is merely a retardation in the normal development of the fetal bones and that there is no change in the osteogenic processes. The osteogenesis is imperfect. In view of this nature of the disease he concludes that it is essential to help the child by careful nursing through the first most dangerous period of life and to protect it particularly against those hazards which may lead to an infection of the air passages and the lung. This demand is the more justified since the clinical and anatomic factors indicate that with this type of treatment the life of otherwise healthy children can be preserved.

Serologic Investigations Following Vaccination with Whooping Cough Bacilli—Keller studied the theoretical foundations of active immunization against whooping cough. By means of the complement fixation test he examined the antigenic action of ten different whooping cough vaccines that had been prepared according to various methods. The investigations revealed that the efficacy of the vaccination, if judged on the basis of the antibody titer produced, depends largely on the manner of application, the total dose, and, particularly, on the mode of preparation of the vaccine. It was found that (1) the bacillary vaccines are superior to the vaccines in which the bacilli have been dissolved (2) the antigenic action of the various strains of the bacillus differs greatly in human subjects and the toxicity in the animal experiment is no measure for this (3) monovalent vaccines from a potent antigenic strain are better and more reliable than polyvalent vaccines that are composed of strains of various potency (4) the excess over

a certain total dose does not improve the results in persons who are constitutionally poor antibody formers. A small percentage of vaccinated persons, even in case of optimal vaccination, are more or less refractory to antigenic action. The author did not detect a relationship between the capacity to form antibodies and the type of blood group or the blood factors M and N. Even nurslings form a considerable number of antibodies in response to a suitable vaccination. The curve indicating the antibody content increases before the tenth day after the first vaccination, it usually reaches its maximum between the tenth and the fourteenth day and after that gradually subsides again so that usually at the end of twenty weeks (the duration varies greatly) the complement fixation reaction is again negative.

Phosphatolysis in Human Erythrocytes—Suntham investigated phosphatolysis in human erythrocytes, using heparinized blood in the tests. 1 He found that carbon dioxide produces the greatest acceleration of phosphate cleavage but that other acids may take its place, for citric acid, pyruvic acid, hydrochloric acid, acetic acid and lactic acid appeared in the four hour value. 2 Sodium fluoride, sodium oxalate and the higher concentrations of citric acid inhibit phosphatolysis, and this inhibitory effect cannot be completely counteracted by carbon dioxide. 3 The alkali cations have no effect on phosphatolysis, whereas the alkaline earths have an inhibiting effect. However, this inhibition can be compensated by carbon dioxide. 4 It appears that the principle of the exchange of anions is of greater importance in the interpretation of phosphatolytic processes than is the pH. 5 In the heparinized blood a lively glycolysis takes place without disappearance of phosphate. The organic phosphorus compounds are probably further decomposed by unimpaired erythrocytes with such rapidity that binding and composition remain in equilibrium. The more lactic acid develops, the greater the cleavage. 6 The theory of the inhibiting action of glycolysis on phosphatolysis does not apply to intact erythrocytes. The irradiation of heparinized blood with ultraviolet rays was without influence on the phosphate cleavage.

Lead in Duodenal Contents in Lead Poisoning—Alyaydin and Peregud investigated the lead content of the duodenal juice in twenty-eight cases of existing or suspected lead poisoning and in five normal controls. The method consisted of reducing the organic matter to ash precipitating the lead from the ash with hydrogen sulfide treating it with potassium bichromate and determining the resulting lead chromate iodometrically. They found that lead was present in the duodenal contents in cases of lead poisoning with about the same frequency as in the urine. It may be present in the urine alone or in the duodenal contents alone. Its concentration in the duodenal contents was considerably greater than in the urine. In about one third of the cases lead was found in the duodenal contents, when it was absent in the urine, in amounts sufficient not to leave any doubt as to its pathologic significance in the presence of other symptoms. They conclude that the finding of lead in the duodenal contents may, in the absence of other symptoms of lead intoxication, lead to a correct diagnosis. The test is only of a relative value since it may be negative in the presence of unmistakable signs of lead intoxication. The authors believe that the method opens up new perspectives in the study of lead poisoning. It may on further investigation throw light on the circulation of lead in the organism and on the mechanism of its excretion by the duodenum. They likewise suggest that the removal of some of the lead by the duodenal tube may be of value in the treatment.

*Thyroid Disturbances and Arthritis H. J. Viersma—p. 3264

Danger of Duck Paratyphoid for Man A. Charlotte Ruys—p. 3272

Thyroid Disturbances and Arthritis—Viersma states that the conditions which have called attention to a possible connection between the thyroid and arthritis are (1) the frequent occurrence of arthritis in youth in goiter countries, (2) the frequent observation of low basal metabolism in chronic arthritis and (3) the favorable influence of thyroid extract in some cases of chronic arthritis. Although it has seemed reasonable enough to connect arthritis with hypothyroidism, until lately it was not known that there are also cases in which hyperthyroidism is the undoubted cause of arthritis. The author describes the history of a man, aged 52, who suffered from exophthalmic goiter and developed in the course of six or seven weeks total fixation of both shoulder joints with severe pains radiating to the arms and atrophy of the shoulder and upper arm muscles which rendered him completely helpless. Suspicion was directed toward hyperthyroidism and attention called to Duncan's report of 292 cases of hyperthyroidism with articular disturbances, in eighty-five of which an etiologic connection was accepted between the two disorders. While any other of the usual treatments failed in these cases, subtotal removal of the thyroid brought improvement, frequently within forty-eight or seventy-two hours after the intervention. In the present case, after a preliminary twelve day treatment with di-iodotyrosin (3.5 di-iodo-4-oxypyphenylalanine), subtotal thyroidectomy caused disappearance of the pains in thirty six hours. Follow-up examination three months later showed a 45 degree abduction in the shoulders and a 30 degree anteroposterior movement with a slight degree of rotation to the left but none to the right. Atrophy of the deltoid and of the supraspinatus was still marked, but the patient was ready to resume his occupation.

*Benign Meningitis H. Björk—p. 428.

Benign Meningitis—Björk reports twelve cases of syphilitic meningitis treated since 1933. In one case the meningitis set in with grave symptoms on the fourth day of an acute polyarthritis and receded in a few days. Six cases occurred simultaneously with or a couple of days after the onset of parotitis. The general condition was relatively little affected, although there were marked changes in the spinal fluid in three of the cases. The cell count varied from 65 to 950, the pleocytosis was mononuclear. Seven cases were complications connected with an influenza-like disorder, appearing with chills and high temperature, in most of the cases after apparent recovery from the basic disorder. During the latent period the patients had felt tired and apathetic. In two instances the clinical picture was atypical, with almost exclusively psychical symptoms in the one, suggestive of a schizophrenia, and in the other a paralysis of the bladder at the start in the other. In three cases there was a transitory disturbance of the extremities. In one case there was a roseola-like exanthem and in another diarrhea, symptoms reported in epidemic serous meningitis in other countries. All the patients recovered, but in three the course was protracted, in one, lumbar puncture was done eleven times, in another, twenty-five times, and in one a transitory cachexia developed.

Cancer in Tuberculosis and Tuberculosis in Cancer—Strandberg's material of 1,206 cases of cancer and 1,806 cases of tuberculosis out of 5,366 necropsies from 1929 to 1935 shows that cancer and active tuberculosis occurred simultaneously more often than they would occur if the disorders were independent of each other. This holds particularly in the cases in which tuberculosis has been more active or more developed.

THE EARLY TREATMENT OF POLIO- MYELITIS AND THE IMPORTANCE OF PHYSICAL THERAPY

CHAIRMAN'S ADDRESS

ARTHUR T LEGG, MD
BOSTON

The recent outbreak of poliomyelitis in Massachusetts has brought to my mind again the necessity of stressing the importance of good after-care. Previously I have written and said a great deal on general follow-up treatment. Now I should like to bring out the benefits to be derived from a long period of competent treatment, namely, the prevention of deformities and the regaining of muscle power.

As soon as the first or acute stage is over, that is, when the temperature has returned to normal and the muscles have shown definite paralysis or weakness, orthopedic treatment should begin immediately, for it is then that contractures must be and can be prevented by holding the various affected parts in a neutral position, thus stopping all strain on the affected muscle.

In immobilizing the legs and arms, one must remember that the neutral position should not be held so continually, or the joints may become stiff. I recently saw a pathetic example of this. A boy whose onset of poliomyelitis was in August 1935, with involvement of the legs, had had solid plasters put on both. They were kept on for six months with the result that when they were removed the knee joints had so stiffened that it was possible to get only a few degrees of flexion in either knee.

For this immobilization, I prefer for the legs posterior wire splints or bivalved plasters, they hold the legs in a neutral position but can be removed easily. I make it a rule to remove the posterior wire splints twice a day and let the patient flex his knee if he can. If he is unable to do this, it should be done manually within the limits of sensitiveness.

With deltoid and arm involvement, simple wire splints may be made to hold the arms in abduction with the elbows flexed or extended according to the involvement of the biceps and triceps while the patient is recumbent, that is, holding the arm in extension if the triceps is weak or in flexion if the biceps is weak, or part time in flexion and part time in extension if both are weak. When the patient is over the recumbent stage and is allowed to sit up, the arm should still be kept up on an abduction or platform splint to support the deltoid. If there is any involvement of the trunk muscles, these also should be supported by a corset.

Sensitiveness of the patient should be relieved as soon as possible in order to start muscle training. I have found that hot wet packs and hot baths given two or three times a day for fifteen minutes help best to shorten this stage. Dry heat may be applied, but it is my experience that moist heat is more effective. I often have patients put in the Hubbard tub even before the sensitiveness is entirely over with the water at 100-104 F to take the place of a hot pack and allow the patient some slight movement to prevent the stiffening of the joints.

At the same time rest is essential and patients should be moved as little as possible.

No muscle activity should be allowed until this stage of sensitiveness is over, and then a complete muscle examination should be made and muscle training can be started. Fatigue of the involved muscles must be carefully watched for, lest in becoming overtired they become weakened.

Rapid regaining of power in one group of muscles over its opposing group will necessitate changes in exercises to prevent unbalance, therefore frequent muscle examinations must be made in order that a true and complete muscle picture of the whole limb may be visualized at all times, to guide correct muscle training. It is my rule to make a complete muscle examination every month for four months, every two months for two examinations, every four months for five years, and then every six months.

I mention here the under water treatment of poliomyelitis. From the buoyancy of the water patients are relieved of the influence of gravity and friction, making it possible to do exercises much more easily than out of water. This affords a sense of accomplishment out of proportion to the actual ability of the weakened muscles, which stimulates the interest and effort of the patient. A wider range of activity other than table exercise is possible without strain. This diversion lessens the possibility of going stale during prolonged treatment. Body balance is learned more easily and walking may be practiced much earlier than outside. This benefit is eventually carried over out of water and prepares the patients for the adjustment of learning to walk in braces.

When shall patients with involvement of the legs be allowed to walk? Patients who with only moderate weakness are making constant gain in muscle power should be, I believe, kept off their feet for a long time, even nine or ten months, since if they are allowed to walk it will be impossible to control their activities. They will overdo and show a loss in muscle power from fatigue. If a patient, however, with moderate or extensive weakness shows but little or no return of power, I believe that braces should be applied even after six or seven months.

Many physicians are too prone to leave the treatment of poliomyelitis patients to their physical thera-

pists Some are capable of taking this responsibility, but I feel that it is important that the physician assume the entire supervision of the case throughout its course

Having discussed the importance of immediate and thorough after-care, I shall present the information I

mal, ninety-seven, or 197 per cent, had moved, died, or had been transferred elsewhere for treatment. 164, or 33 per cent, are still under my supervision at the clinic

Of these 164 cases, 109 are omitted because they were operative cases and I am measuring gain in

Chart 1—Result of good and poor treatment in a case of arm and leg involvement C P a girl aged 3 years onset in September 1927 Solid line, good treatment broken line poor treatment

Chart 2—Course in a case in which treatment was given for four years interrupted for two years and given for two years L S a boy aged 9 years onset in July 1927 Solid line, receiving treatment broken line not receiving treatment

Chart 3—Course in a case receiving and not receiving treatment A P a girl aged 2 years onset in September 1927 Solid line, receiving treatment broken line not receiving treatment

have collected from my clinic cases concerning the amount of benefit derived from a long period of after-care I shall show that treatment after even five years is not just a preventive treatment By that I mean that it is not just to prevent deformities due to muscle

in muscle power, therefore the cases are limited to fifty-three

These fifty-three cases are divided into three classes of treatment, good, medium and poor In classifying these cases I have taken into consideration record of

Chart 4—A case with poor and good treatment F T a boy aged 1 year onset in September 1927 Solid line good treatment broken line poor treatment

Chart 5—A case with good treatment for eight years J S a boy aged 7 years onset in September 1927

Chart 6—Yearly percentage rate of improvement in fifty-three cases

contractures, which is reason enough to continue treatment, but that even after five years definite gain in muscle power still can be made I am using the figures compiled from the cases in which the onset occurred

attendance to the main and field clinics and faithfulness of home treatment The latter information based on the report of the family and the physical therapist

Chart 7—Yearly percentage of involvement in fifty-three cases of paralysis of the legs arms and trunk

Chart 8—Yearly percentage of improvement in paralysis of the legs and trunk with good medium and poor treatment

Chart 9—Yearly percentage of improvement of the arms with fair and medium treatment

in 1927 There were 496 cases reported to the Harvard Infantile Paralysis Clinic the onsets of which were in 1927 Of these 496 patients by Jan 1 1934, 167, or 33.6 per cent had been discharged or left practically normal or normal, sixty-eight or 13.7 per cent left or were discharged for noncooperation and were not nor-

In getting the percentage figures of the average amount of involvement, I graded the muscle as follows

- A normal muscle was graded 0 paralysis
- A good muscle was graded 1 paralysis
- A fair muscle was graded 2 paralysis

A poor muscle was graded 3 paralysis
A trace muscle was graded 4 paralysis
A gone muscle was graded 5 paralysis

The total number of muscles of the legs and arms left and right according to the 1927 muscle charts equal forty-six. Therefore, if each of the forty-six muscles was graded a "gone muscle," total paralysis of the legs and trunk would equal five times forty-six, or 230. The same holds true with the arm muscles, total paralysis equaling 290. A yearly muscle examination of each case was figured on this basis.

On the graphs it will be seen that good treatment is shown by a solid line and poor treatment by a broken line. It is of interest to note that, as soon as treatment was discontinued, muscle power weakened even after five years of care, after a return of the same cases to steady treatment, muscle power gained even within the ninth year after onset. This is shown by charts 1, 2 and 3.

In chart 4 the patient showed increased muscle weakness during the first year with no treatment, which is, though perhaps not a common occurrence, at least contrary to the opinion that all cases will improve at first regardless of treatment.

Chart 5, of a patient receiving good treatment steadily for nine years, shows an absolutely steady gain in muscle power right on to 1936.

The averaging of these fifty-three cases proves to my mind that steady follow-up treatment is not only beneficial in preventing deformities but equally important in positive increase in muscle power.

Here the graphs read as 0 improvement at the bottom of the graph, which would be the first examination, and 100 per cent improvement, or normal, at the top. Therefore chart 6 shows that the legs and trunk, over a period of nine years, improved 75 per cent on an average and the arms 80 per cent. It is of great interest, I believe, to see that the average goes slowly but steadily up toward normal even in 1935, nine years after the onset. In other words, the average paralysis of the legs and trunk, which at onset was 25 per cent, dropped down to only 8 per cent and the arms from onset of 20 per cent paralysis to 6 per cent paralysis (chart 7).

But, definite as these averages are, the division of the cases into good, medium and poor treatment and their according averages leaves my mind without a doubt that correct and steady follow-up care is of tremendous importance long after the onset (charts 8 and 9). They show the average yearly percentage of improvement of the legs and arms according to their class of treatment. Patients with leg and trunk paralysis receiving good treatment improved 81 per cent in nine years, patients receiving medium treatment improved 74 per cent, and those receiving poor treatment improved but 53 per cent. The arms improved in about the same proportions. Patients receiving good treatment improved 84 per cent, those receiving medium treatment improved but 73.6 per cent. There were two poor treatment cases which would not make a true average and are therefore omitted. Charts 8 and 9 not only have shown the importance of long continuous treatment but also refer back to the first point the importance of immediate good treatment.

During the first year, patients with leg and trunk paralysis receiving good treatment improved 61 per cent, those receiving medium treatment only 48 per cent and those receiving poor treatment but 44 per cent. Again the arms show the same, the patients

receiving good treatment improving 74 per cent and those receiving medium treatment but 48 per cent in the first year.

There is some spontaneous recovery of muscle power following an attack of poliomyelitis, owing to the edema of the cord. Many patients severely weakened or paralyzed make a very rapid and often complete recovery of muscle power even without treatment. It is my belief that there is no spontaneous recovery after six months. Late return of power may occur when a muscle has been put out of commission by more rapid recovery of its opponent and contracture. This being relieved, the muscle will immediately come back to power.

SUMMARY

Complete rest and immobilization with limbs in the neutral positions should be insisted on as soon as the paralysis or weakness occurs, to prevent contracture and to aid in the relief of the sensitive stage. A complete muscle examination should be made as soon as the sensitive stage is over and from this the muscle training should be planned. A careful check up on the gain or loss of muscle power should be made at definite intervals. The careful check up on the muscles affected should be carried out for years.

I believe my graphs show conclusively that while the greatest rate of gain is in the first year, with treatment a real progress can be made over a long period of years.

319 Longwood Avenue.

TEACHING PSYCHIATRY IN THE MEDICAL SCHOOL GENERAL HOSPITAL

A PRACTICAL PLAN

EDWARD G. BILLINGS, M.D.

Assistant Professor of Psychiatry and Director Psychiatric Liaison
Department University of Colorado and School of Medicine
and Hospitals
DENVER

The 1932 survey of sixty-eight medical schools in the United States and Canada, made by Ebaugh¹ for the National Committee for Mental Hygiene, indicated that 42 per cent of schools had not, at that time, developed clinical facilities for general psychiatric teaching, and that only eight schools had developed psychiatric liaison with the clinical departments of the general hospital. Unquestionably, many schools, since this survey was made, have begun developing more adequate facilities for training the medical student and intern in the diagnosis and treatment of the relatively large number of psychiatric cases commonly coming to the general practicing physician (generally estimated at from 35 to 75 per cent of the general physician's patient load). Suffice it to say that, since the present-day trend of modern medicine is toward a more firm coalescence of the fundamental scientific principles, clinical procedures and teaching methods of psychobiology and psychiatry with those of other departments of medical schools, the general hospital is being and will continue to have to be used more and more as a medium of procedure.

Such liaison projects in general hospitals are, however, relatively few and naturally differ considerably in

¹ The Psychiatric Liaison Department is a part of the Department of Psychiatry, Colorado University School of Medicine, financed by the Rockefeller Foundation.
² Ebaugh, F. G. Psychiatric Education in America, a Confidential Report to the National Committee for Mental Hygiene, 1932.

their working methods, depending on the many situational factors among which they are developed. The experiences of others have been exceedingly helpful in organizing and developing such an enterprise in the University of Colorado General Hospital. It is with this in mind that this exposition of the development of the Psychiatric Liaison Department of the University of Colorado Medical School and Hospitals is offered, in the hope that our experiences may give a modicum of helpfulness to those just beginning, or about to begin, similar work. In this paper no attempt is made to do more than sketch the general situation, some of the more prominent objectives, the mode of procedure and the difficulties and successes.

THE SITUATION

The University of Colorado School of Medicine and Hospitals, which is located in Denver (population 287,861), the capital of the state of Colorado (population 1,035,791), gives all four years of medicine and accommodates fifty students per class. The group of buildings serving the school includes a medical school building which is connected with the State General Hospital of 150 beds, and an outpatient wing that houses some twenty clinics. Uniting these is a central administration building in which are located the school administrative offices, the library of some 19,000 volumes and 321 current journals, a museum, an amphitheater, centralized laboratory and research units, and the Child Research Council under the directorship of Dr. Alfred H. Washburn. The State Psychopathic Hospital of eighty beds occupies a separate building adjacent to the school and the General Hospital. The physical set-up is not far different from that of the average medical school and state general hospital except for the excellent psychiatric facilities which are to be had in the Colorado Psychopathic Hospital, under the direction of Dr. Franklin G. Ebaugh.

During the past three years the average yearly admission rate to the General Hospital was 4,366. To the outpatient dispensary there came 9,448 new cases, and a total of 57,900 return visits were made during the year 1934-1935.

Prior to mid 1934, the psychiatric problems in the Colorado General Hospital and Dispensary were seen by the staff members and Commonwealth Fellows of the Psychopathic Hospital. This consultation service, over a period of eight years, did much to pave the way for the more recent ingrowth of psychobiology and psychiatry in the thinking and activity of the medical-surgical fields of this locus. In September 1934 a grant by the Rockefeller Foundation made possible the organization of a full time department of psychiatry in the General Hospital wards and dispensary. This department is called the Psychiatric Liaison Department of the Colorado General and Psychopathic Hospitals and is manned by a full time staff consisting of the psychiatrist, a social service worker and a secretary. A Commonwealth Fellow from the Psychopathic Hospital serves as the psychiatrist's assistant on a three months part time basis. It is concerning the development and functions of this liaison department during the past eighteen months that the present report is made.

AIMS AND OBJECTIVES

The not atypical attitude of "I'm from Missouri" on the part of the General Hospital visiting staff, resident staff and students and the feeling that psychobiology and psychiatry are not for the "general man" prevailed

at the inception of this liaison project. This feeling of apparent skepticism on the part of nonpsychiatrists might have been taken as a confronting difficulty and was interpreted as one of being willing to be convinced that psychiatry could be used practically and advantageously in a general hospital. It therefore seemed imperative that the program be demonstrative and not one of mere "preaching." We have found that such a program is of the greatest importance in creating a curiosity on the part of the nonpsychiatrist and leading to a spontaneous search for facts with an emotional as well as an intellectual acceptance of them.

With this type of program to be undertaken the utilization of limited and narrow aims seemed somewhat hazardous. In a general hospital the psychiatrist constantly has to maintain the clinical perspective of his nonpsychiatric colleagues as well as that of his own particular specialty and cannot possibly anticipate an amalgamation, such as has been referred to, by starting with a horizon contracted to a mere interesting case or a lone special project. It seemed essential, therefore, that our aims be formulated for realization far in the future and that any objectives to be undertaken in terms of the present or near future must always fall in line with them and at the same time be fluid enough to fit the ever changing situation.

The department was organized around and developed on three rather broad aims which we hope will prove adequate:

- 1 To sensitize the physicians and students to the opportunities offered them by every patient, no matter what complaint or ailment is present, for the utilization of a "common sense" psychiatric approach for the betterment of the patient's condition, and for making that patient better fitted to handle his problems—somatic or personality determined or both.

- 2 To establish psychobiology as an integral working part of the professional thinking of physicians and students of all branches of medicine.

- 3 To instill in the physicians and students the need for patient-public has for a more tangible and practical concept of personality and sociological functioning. This, not so much in the sense of "prevention" of mental and personality disorders per se, but rather in the sense of prevention of false thinking, misconception, misunderstanding, folklore and tabus which make it difficult for the patient to accept help or to allow the physician to be of help.

A CONFRONTING ATTITUDE, PROCEDURE, SOME GENERAL RESULTS

To the beginning intern in and the visiting physician to a general hospital, the first evaluation of the importance of a new clinical department is based, seemingly, on case turnover. If the psychiatrist picks his cases in any way designates what is or is not "his case," the project loses the interest of his confreres. During the first year the department took "everything" referred. Of this case load, on thorough examination, approximately 12 per cent of the patients were found to have some body disorder either purely incidental to and playing no role in the psychiatric problem presented, presenting only a minor contributive part. Between 5 and 6 per cent of the cases referred as "pre-emptive" "functional" problems during that year proved not to be psychiatric disorders but real somatic diseases ranging from pulmonary tuberculosis, cholecystitis, appendicitis, planus to brain tumor, which had been entirely overlooked because the case somewhat resembled a psychiatric one and usually was designated in lay terms as "hysteria" or "neurasthenia." These cases, unassumingly examined, diagnosed, formulated and treated, which treatment in keeping with medical opinion...

outlined, did a great work in stimulating the internist, surgeon and student to look further before referring his patients. The result has been that in looking further the nonpsychiatrist has asked for aids in studying personality, has used them and finds that in employing them he gets the "feel" of so-called functional personality disorders. Thus, then, paves the way for a better and more acceptable assimilation and utilization of the content of the case formulations which the department, as time goes on, endeavors to make more complete and instructive for the referring physician. In regard to these formulations, we try to fulfil four obligations: first, to arrange and group the complaint of the patient so that it presents a clear and concise verbal picture, second, to evolve the complaint in a simple but clear fashion to sound plausible and sensible and to stimulate an urge to know more of the details, third, to avoid nosologic psychiatric diagnosis in favor of a summarizing sentence or two that neutralizes any antipathy that might exist for "big words," and, fourth, to outline treatment in as clear, concise and all encompassing a manner as is possible, pointing out dangers and difficulties and ways of evaluating success. Through progress notes written after each treatment interview with the patient, as well as through discussions with the attending doctor, the physicians are kept informed as to methods, attainments and failures.

The result is that ordinary deliriums, mild depressions, simple anxiety syndromes and the like are being competently handled more and more by students, interns and the visiting physicians. Furthermore, potential personality reactions such as postoperative excitement, delirium, panic, early depressions, schizophrenic reactions and some of the "part disorders" (i.e., psychoneuroses) are being recognized by them. Thereupon the psychiatrist is called in to collaborate on the medical, surgical or obstetric procedures best fitted to avoid stirring up more profound disorders and for ameliorating those existent. For example, the ophthalmologist now often calls for the psychiatrist to assist him in determining whether a visual disturbance is a result of a combination of refractive error and a physiologic phenomenon of a tension state and, if such exists, whether refraction should precede or follow the psychiatric job of ameliorating the tension. Or the gynecologist, for instance, is beginning to ask for assistance in deciding whether a certain patient can or cannot be given douches for a local vaginal condition without stirring up more personality determined pelvic sensations. Thus, one clinician after another has learned to avail himself of the department, so that at the present time our clinical material is drawn from 61 per cent of the outpatient clinics and from all the wards of the General Hospital.

PSYCHIATRY IN THE OUTPATIENT DEPARTMENT OF THE GENERAL HOSPITAL

In the outpatient department the psychiatrist works each morning in the medical clinic, since more space is available here and because it is from this clinic that most of our referrals come. At least one new case and an average of two to four cases previously examined and under treatment are seen daily. The new cases, despite the fact that they have been examined physically and neurologically, are reexamined in these fields as well as psychiatrically. This keeps the psychiatrist medically minded, makes the referring physician more respectful of psychiatry, and brings the student face to face with the fact that psychiatry and the other

branches of medical science cannot be segregated. It is frequently felt that the psychiatrist must have a special and private environment in which to examine his patient. This, of course, is ideal. In our outpatient department, however, we have to work in a booth that is not sound proof. It has been our experience that this condition has helped a great deal in teaching the internist by indirect means, since it is possible for the physician working in the booth next door to overhear the examination and treatment of the case he has referred to us. After the case is examined, our observations are discussed with the referring physician, social workers and any others who are interested. A mutual understanding is reached and treatment is planned. A decision is then attained as to who is to be in charge of the case. Frequently the referring physician wishes to learn the management of this personality problem. He is directed to the literature, regular discussions with the psychiatrist are planned and he is helped in formulating the case for himself. It is the consensus of the physicians in our medical dispensary that at least 37 per cent of all new cases admitted to the medical outpatient clinic are psychiatric problems. Our department is able to see only approximately 20 per cent of the new cases. The remainder are carried by the internists under our supervision and guidance. Cases presenting good teaching and research problems are sent to the Psychopathic Hospital as these are desired by the staff of that unit.

TEACHING THE STUDENT PSYCHIATRY IN THE OUTPATIENT MEDICAL CLINIC

The General Hospital psychiatrist comes in contact, through the clinical cases, with the student senior clerks, who are assigned in rotating groups of eight to medicine, in the outpatient department and the wards. Each student, before presenting himself for clinical work, is required to study a compendium in which are outlined the rudiments of psychobiology, the methods of examination and a simple, descriptive outline of the differential diagnosis. Each student group is carefully instructed, in a special two hour meeting, how to elicit the facts from the patient and how to sort and use them. Each student spends several two hour periods of his clinical medical outpatient time with the psychiatrist. Since we see our outpatients by appointment, it is possible to choose cases that are best adapted for teaching and that illustrate points made in the general lecture course, and to assign them to students a week ahead of the examination date. If the student clerk has at any previous time seen the patient in question in any clinic of the outpatient department, he is assigned that case for psychiatric study. He is responsible for a thorough knowledge of the case as given by the data thus far collected, including other clinical examinations, any laboratory reports and the material our social service department has collected from social agencies, schools, employers or relatives. During his six weeks in medical clinic, each student has from three to five opportunities to examine new cases. At the first meeting with a patient he listens to the psychiatrist as he obtains the data from the patient, records it, formulates it and outlines the therapy. At the second meeting the clerk is required to record the data under supervision as the psychiatrist elicits it. The third meeting finds the student doing the whole job with the psychiatrist sitting by as an observer and assistant. The complaint of the patient is carefully and completely elicited. It has been our experience that if the student can be led to get these most important data his curiosity will usually compel

their working methods, depending on the many situational factors among which they are developed. The experiences of others have been exceedingly helpful in organizing and developing such an enterprise in the University of Colorado General Hospital. It is with this in mind that this exposition of the development of the Psychiatric Liaison Department of the University of Colorado Medical School and Hospitals is offered, in the hope that our experiences may give a modicum of helpfulness to those just beginning, or about to begin, similar work. In this paper no attempt is made to do more than sketch the general situation, some of the more prominent objectives, the mode of procedure and the difficulties and successes.

THE SITUATION

The University of Colorado School of Medicine and Hospitals, which is located in Denver (population 287,861), the capital of the state of Colorado (population 1,035,791), gives all four years of medicine and accommodates fifty students per class. The group of buildings serving the school includes a medical school building which is connected with the State General Hospital of 150 beds, and an outpatient wing that houses some twenty clinics. Uniting these is a central administration building in which are located the school administrative offices, the library of some 19,000 volumes and 321 current journals, a museum, an amphitheater, centralized laboratory and research units, and the Child Research Council under the directorship of Dr. Alfred H. Washburn. The State Psychopathic Hospital of eighty beds occupies a separate building adjacent to the school and the General Hospital. The physical set-up is not far different from that of the average medical school and state general hospital except for the excellent psychiatric facilities which are to be had in the Colorado Psychopathic Hospital, under the direction of Dr. Franklin G. Ebaugh.

During the past three years the average yearly admission rate to the General Hospital was 4,366. To the outpatient dispensary there came 9,448 new cases, and a total of 57,900 return visits were made during the year 1934-1935.

Prior to mid 1934, the psychiatric problems in the Colorado General Hospital and Dispensary were seen by the staff members and Commonwealth Fellows of the Psychopathic Hospital. This consultation service, over a period of eight years, did much to pave the way for the more recent ingrowth of psychobiology and psychiatry in the thinking and activity of the medical-surgical fields of this locus. In September 1934 a grant by the Rockefeller Foundation made possible the organization of a full time department of psychiatry in the General Hospital wards and dispensary. This department is called the Psychiatric Liaison Department of the Colorado General and Psychopathic Hospitals and is manned by a full time staff consisting of the psychiatrist, a social service worker and a secretary. A Commonwealth Fellow from the Psychopathic Hospital serves as the psychiatrist's assistant on a three months part time basis. It is concerning the development and functions of this liaison department during the past eighteen months that the present report is made.

AIMS AND OBJECTIVES

The not atypical attitude of 'I'm from Missouri' on the part of the General Hospital visiting staff, resident staff and students and the feeling that psychobiology and psychiatry are not for the general man prevailed

at the inception of this liaison project. This feeling of apparent skepticism on the part of nonpsychiatrists might have been taken as a confronting difficulty. I was interpreted as one of being willing to be convinced that psychiatry could be used practically and advantageously in a general hospital. It therefore seemed imperative that the program be demonstrative and not one of mere "preaching." We have found that such a program is of the greatest importance in creating a curiosity on the part of the nonpsychiatrist and leading to a spontaneous search for facts with an emotional as well as an intellectual acceptance of them.

With this type of program to be undertaken the utilization of limited and narrow aims seemed somewhat hazardous. In a general hospital the psychiatrist constantly has to maintain the clinical perspective of his nonpsychiatric colleagues as well as that of his own particular specialty and cannot possibly anticipate an amalgamation, such as has been referred to, by starting with a horizon contracted to a mere interesting case or a lone special project. It seemed essential, therefore, that our aims be formulated for realization far in the future and that any objectives to be undertaken in terms of the present or near future must always fall in line with them and at the same time be fluid enough to fit the ever changing situation.

The department was organized around and developed on three rather broad aims which we hope will prove adequate:

- 1 To sensitize the physicians and students to the opportunities offered them by every patient, no matter what complaint or ailment is present, for the utilization of a "common sense" psychiatric approach for the betterment of the patient's condition, and for making that patient better fitted to handle his problems—somatic or personality determined or both.

- 2 To establish psychobiology as an integral working part of the professional thinking of physicians and students of all branches of medicine.

- 3 To instill in the physicians and students the need the patient-public has for a more tangible and practical conception of personality and sociological functioning. This, not so much in the sense of "prevention" of mental and personality disorders per se, but rather in the sense of prevention of false thinking, misconception, misunderstanding, folklore and tabus which make it difficult for the patient to accept help or to allow the physician to be of help.

A CONFRONTING ATTITUDE, PROCEDURE, SOME GENERAL RESULTS

To the beginning intern in and the visiting physician to a general hospital, the first evaluation of the importance of a new clinical department is based, seemingly, on case turnover. If the psychiatrist picks his cases in any way designates what is or is not 'his case,' the project loses the interest of his confreres. During the first year the department took "everything" referred. Of this case load, on thorough examination, approximately 12 per cent of the patients were found to have some body disorder either purely incidental to and playing no role in the psychiatric problem present or presenting only a minor contributive part. Between 5 and 6 per cent of the cases referred as pre-entirely "functional" problems during that year proved not to be psychiatric disorders but real somatic disorders ranging from pulmonary tuberculosis, cholecystitis, and pes planus to brain tumor, which had been entirely overlooked because the case somewhat resembled a psychiatric one and usually was designated in such terms as "hysteria" or "neurasthenia." These cases, unassumingly examined, diagnosed, formulated and treated, which treatment in keeping with medical opinion was

outlined, did a great work in stimulating the internist, surgeon and student to look further before referring his patients. The result has been that in looking further the nonpsychiatrist has asked for aids in studying personality, has used them and finds that in employing them he gets the "feel" of so-called functional personality disorders. This, then, paves the way for a better and more acceptable assimilation and utilization of the content of the case formulations, which the department, as time goes on, endeavors to make more complete and instructive for the referring physician. In regard to these formulations, we try to fulfil four obligations: first, to arrange and group the complaint of the patient so that it presents a clear and concise verbal picture, second, to evolve the complaint in a simple but clear fashion to sound plausible and sensible and to stimulate an urge to know more of the details, third, to avoid nosologic psychiatric diagnosis in favor of a summarizing sentence or two that neutralizes any antipathy that might exist for "big words," and, fourth, to outline treatment in as clear, concise and all encompassing a manner as is possible, pointing out dangers and difficulties and ways of evaluating success. Through progress notes written after each treatment interview with the patient, as well as through discussions with the attending doctor, the physicians are kept informed as to methods, attainments and failures.

The result is that ordinary deliriums, mild depressions, simple anxiety syndromes and the like are being competently handled more and more by students, interns and the visiting physicians. Furthermore, potential personality reactions such as postoperative excitement, delirium, panic, early depressions, schizophrenic reactions and some of the "part disorders" (i.e., psychoneuroses) are being recognized by them. Thereupon the psychiatrist is called in to collaborate on the medical, surgical or obstetric procedures best fitted to avoid stirring up more profound disorders and for ameliorating those existent. For example, the ophthalmologist now often calls for the psychiatrist to assist him in determining whether a visual disturbance is a result of a combination of refractive error and a physiologic phenomenon of a tension state and, if such exists, whether refraction should precede or follow the psychiatric job of ameliorating the tension. Or the gynecologist, for instance, is beginning to ask for assistance in deciding whether a certain patient can or cannot be given douches for a local vaginal condition without stirring up more personality determined pelvic sensations. Thus, one clinician after another has learned to avail himself of the department, so that at the present time our clinical material is drawn from 61 per cent of the outpatient clinics and from all the wards of the General Hospital.

PSYCHIATRY IN THE OUTPATIENT DEPARTMENT OF THE GENERAL HOSPITAL

In the outpatient department the psychiatrist works each morning in the medical clinic, since more space is available here and because it is from this clinic that most of our referrals come. At least one new case and an average of two to four cases previously examined and under treatment are seen daily. The new cases, despite the fact that they have been examined physically and neurologically, are reexamined in these fields as well as psychiatrically. This keeps the psychiatrist medically minded, makes the referring physician more respectful of psychiatry, and brings the student face to face with the fact that psychiatry and the other

branches of medical science cannot be segregated. It is frequently felt that the psychiatrist must have a special and private environment in which to examine his patient. This, of course, is ideal. In our outpatient department, however, we have to work in a booth that is not sound proof. It has been our experience that this condition has helped a great deal in teaching the internist by indirect means, since it is possible for the physician working in the booth next door to overhear the examination and treatment of the case he has referred to us. After the case is examined, our observations are discussed with the referring physician, social workers and any others who are interested. A mutual understanding is reached and treatment is planned. A decision is then attained as to who is to be in charge of the case. Frequently the referring physician wishes to learn the management of this personality problem. He is directed to the literature, regular discussions with the psychiatrist are planned and he is helped in formulating the case for himself. It is the consensus of the physicians in our medical dispensary that at least 37 per cent of all new cases admitted to the medical outpatient clinic are psychiatric problems. Our department is able to see only approximately 20 per cent of the new cases. The remainder are carried by the internists under our supervision and guidance. Cases presenting good teaching and research problems are sent to the Psychopathic Hospital as these are desired by the staff of that unit.

TEACHING THE STUDENT PSYCHIATRY IN THE OUTPATIENT MEDICAL CLINIC

The General Hospital psychiatrist comes in contact, through the clinical cases, with the student senior clerks, who are assigned in rotating groups of eight to medicine, in the outpatient department and the wards. Each student, before presenting himself for clinical work, is required to study a compendium in which are outlined the rudiments of psychobiology, the methods of examination and a simple, descriptive outline of the differential diagnosis. Each student group is carefully instructed, in a special two hour meeting, how to elicit the facts from the patient and how to sort and use them. Each student spends several two hour periods of his clinical medical outpatient time with the psychiatrist. Since we see our outpatients by appointment, it is possible to choose cases that are best adapted for teaching and that illustrate points made in the general lecture course, and to assign them to students a week ahead of the examination date. If the student clerk has at any previous time seen the patient in question in any clinic of the outpatient department, he is assigned that case for psychiatric study. He is responsible for a thorough knowledge of the case as given by the data thus far collected, including other clinical examinations, any laboratory reports and the material our social service department has collected from social agencies, schools, employers or relatives. During his six weeks in medical clinic, each student has from three to five opportunities to examine new cases. At the first meeting with a patient he listens to the psychiatrist as he obtains the data from the patient, records it, formulates it and outlines the therapy. At the second meeting the clerk is required to record the data under supervision as the psychiatrist elicits it. The third meeting finds the student doing the whole job with the psychiatrist sitting by as an observer and assistant. The complaint of the patient is carefully and completely elicited. It has been our experience that if the student can be led to get these most important data his curiosity will usually compel

him to understand them by obtaining a thorough history and doing complete examinations. In order to emphasize this, we endeavor to evaluate our treatment accomplishments in terms of complaint changes. About two students out of each group of eight clerks desire to treat some of their cases. They are allowed to do so, always under the guidance of the psychiatrist. One morning a week, only cases previously examined are seen by the psychiatrist. This enables us to discuss perhaps eight or ten cases under treatment with each individual student, to explain what has been done in previous interviews, what we wish to accomplish at the present meeting, how we shall attempt to do it and then to allow him an opportunity to see the actual work. After the interview, a discussion of what we feel we have and have not accomplished and why is always held.

It has been very interesting to note how the students in their required medical, gynecologic, dermatologic and other examinations of patients throughout the dispensary are beginning to record more and more the real complaint of the patient and to evaluate the personality evolution. Now, after twenty months of activity, we notice that in a large majority of cases referred to us the student has already correctly evaluated the case and begun some psychotherapy prior to referral. This has begun to infect the busy visiting clinician, who now frequently comes, usually with his student group, to ask how he should proceed with "such and such a case" that he has in his private practice.

TEACHING THE STUDENT PSYCHIATRY IN THE GENERAL HOSPITAL

The case material and teaching of the students in the wards is handled in a somewhat similar fashion. In this instance we see only cases referred to us for consultation by the resident and visiting staffs. The only insistent requirement here made is that the intern write out a formal request for the psychiatric consultation, formulating the case, not in quasidiagnostic phraseology but in simple facts. As soon as the case is referred to us the student assigned to the case is automatically responsible for the incorporation of a full psychiatric work-up with his regular medical and surgical one. The case is seen either in the wards or in the liaison office and examined physically, neurologically and psychiatrically. The results of these examinations and those of other special tests or examinations are then formulated briefly, particular attention being paid to differential diagnostic points and treatment as outlined. The carrying out of therapy may follow one of three routes. The intern has first choice, if he wishes to try his hand he is allowed to do so with the requirement that he have daily conferences with the psychiatrist. The student may do likewise. If neither wishes to take an active part or if the psychiatrist feels that the problem is too difficult for them they are urged to observe and follow the treatment instituted by the psychiatrist. Once a week the psychiatrist accompanies the visiting internist and his resident staff on ward rounds. Following these rounds all repair to the liaison department offices where all cases are discussed as to points of interest, research problems, teaching, therapeutic opportunities, sociological involvements and means of accomplishing an end satisfactory to all.

Once weekly for two hours we meet the student clerks assigned to the medical wards. At these meetings the students present their cases. The cases are discussed and therapy evaluated. Care is taken to collaborate with the teachings of the internists and

surgeons when nonpsychiatric problems are encountered. A ward walk concludes the hour. At this time the student in charge of the given case is acting master of ceremonies in demonstrating the case and in applying the therapy decided on. The psychiatrist stands by to prevent difficulties from arising and to polish off the exercise. This tends to give the student clerk a feeling of security in himself and certainly a familiarity with the practical application of knowledge gained by other means.

LIAISON TEACHING THROUGH LECTURES

The more formal teaching of psychobiology and psychiatry, as applicable to general practice, is taken up in a lecture course held each week for one hour throughout the entire senior year. In this course the first trimester of twelve hours is spent in reviewing psychobiology and in weaving it into the general clinical and usual didactic courses. In these meetings, which are always accompanied with clinical demonstrations, the participations of the various somatic systems, organs and physiologic processes in personality function are discussed. The second and third trimester lectures are given over to discussions of treatment of the more usual reaction types occurring in the general hospital, dispensary and practice. Once a month, one of the internists joins the psychiatrist in presenting a clinic to the senior class. In this clinic the internist is given the floor for the purpose of emphasizing the importance of psychobiologic concepts and psychiatric principles in everyday medicine, and for emphasizing differential diagnostic points and his need for psychotherapeutic aids.

OTHER LIAISON TEACHING PROJECTS

There are other liaison teaching projects which are not to be considered less important merely because I mention them briefly in closing.

At Colorado University the second year medical student is first initiated into psychiatry through biweekly discussions at the Psychopathic Hospital. As a junior student he receives training in formal psychobiology and psychiatric procedures from Dr. Ebaugh. As a senior, his Psychopathic Hospital work allows for more personal clinical contact with patients through work in the wards and in demonstration clinics. It was necessary to weld this with the work in the General Hospital and to sensitize the junior student to the psychiatric problems common to general medicine and surgery that await him as a senior. In order to do this the liaison psychiatrist is occasionally invited to join Dr. Waring, the professor of medicine, in his regular medical clinic for juniors wherein the clinical demonstration is made of cases taken from the outpatient department and the wards of the General Hospital and showing psychiatric problems.

The psychiatrist of the liaison department once weekly, endeavors to take medical principles and practices and his experiences with psychiatric patients in the General Hospital to the wards of the psychopathic hospital by means of discussions with the physicians in the hospital.

THE SOCIOLOGICAL ASPECT

In an attempt to broaden the student's horizon to include the sociological factors and problems connected with the presenting act of the biologic drama of the patient and to acquaint the student with community resources at his disposal in caring for his patients, we instituted last year what we call "sociopsychiatric conferences." These conferences

were held at irregular intervals during the year and were open to students, nurses and staff members. Such topics as "Educational and Vocational Aspects of Feeblemindedness," "Physical-Medical Disabilities in Dollars and Cents," and "The Physician and the Court" were discussed by from four to six discussants mustered from industry and business, the legal profession, courts, school systems, various medical specialties, and governmental social agencies.

An attempt is being made to impregnate gradually the industries, schools, courts and social agencies with the medicopsychiatric needs of the community and state. A constant effort is made to sensitize the student and hospital physician to the sociological needs of the community, as to how some of the patients' symptoms are repercussions of general economic problems, as to his responsibility to his community and patient, and as to how he can utilize the available resources.

BEDSIDE TEACHING

CONSIDERATION OF THE PATIENT'S EMOTIONAL RESPONSE TO CASE DISCUSSION

EUGEN KAHN, M.D.
AND
GROVER F. POWERS, M.D.
NEW HAVEN, CONN.

The use of the hospital ward and dispensary as the laboratory for the teaching of clinical medicine is a procedure with ancient and approved lineage—a descendant of the master-apprentice relationship which probably antedates formal academic disciplines. In modern times, bedside teaching of the medical student has been emphasized rather more in British than in continental schools, where the didactic lecture system was stressed.¹ In the United States, teaching in the medical schools was for many years largely by lectures and recitations. To Abraham Jacoby (1830-1919), nestor of American pediatrics, great credit is due for early attempts to break away from this method and establish clinical teaching in its laboratory—the bedside.

Reminiscing in 1917, Jacoby² wrote

If ever you will recall for yourself and your friends the first, the very first beginning of medical bedside instruction in America, please tell them of the small college on East 13th Street—I believe 118—which had to close its doors in 1864, a victim of the Civil War, which deprived us of our Southern students. That is part of your American medical history worth remembering. I was permitted to be quite active in that successful enterprise, and utilized my opportunities in preferring my pets, the young patients. My later experience will teach you that successful bedside teaching was almost exclusively pediatric. Thus pediatrics was the example of giving correct medical instruction.

However, it was with the launching of the Johns Hopkins Medical School in 1893 and the impetus given to educational procedures by the example and success of William Osler that clinical clerkships and bedside conferences were established as the sine qua non of clinical instruction.³ Recognition of Osler's important

share in this development in American medical education is evidenced in Cushing's dedication of his biography of Osler.

To Medical Students and particularly to those in America, lest it be forgotten who it was that made it possible for them to work at the bedside in the Wards.

In his valedictory address at Johns Hopkins University, Osler⁴ said

By far the greatest work of the Johns Hopkins Hospital has been the demonstration to the profession of the United States and to the public of this country of how medical students should be instructed in their art. I place it first because it was the most-needed lesson, I place it first because it has done the most good as a stimulating example, and I place it first because never before in the history of this country have medical students lived and worked in a hospital as part of its machinery, as an essential part of the work on the wards.

In saying this, heaven forbid that I should obliquely disparage the good and faithful work of my colleagues elsewhere. But the amphitheater clinic, the ward and dispensary classes are but bastard substitutes for a system which makes the medical student himself help in the work of the hospital as part of its human machinery. He does not see the pneumonia case in the amphitheater from the benches, but he follows it day by day, hour by hour, and he has his time so arranged that he can follow it, he sees and studies similar cases, and the disease itself becomes his chief teacher, and he learns its phases and variations as depicted in the living, and he knows under skilled direction when to act and when to refrain from action, he learns insensibly principles of practice, and he possibly escapes a nickel-in-the-slot attitude of mind, which has been the curse of the profession in the treatment of disease.

And the same with the other branches of the art, he gets a first-hand knowledge which, if he has any sense, may make him wise unto the salvation of his fellows. And all this has come about through the wise provision that the hospital was to be part of the medical school, and it has become for the senior students, as it should be, their college. Moreover, they are not in it on sufferance and admitted through side doors, but they are welcomed as important aids without which the work could not be done efficiently.

There can be no question of the essential value to the clinical student of teaching at the bedside. There the teacher-physician has the opportunity to observe his patient and convey his observations immediately to his student or apprentice, there the teacher can make his student or apprentice familiar with his methods of examination and the student is able to examine the patient under the direction and control of his teacher.

Such teaching developed in the homes of patients, in the hospitals in which patients were housed and nursed and in the dispensaries. One can easily picture one of the teachers in medicine expounding his observations to one student, or to a group of students, in the presence of the patient, and leading a discussion with the students about the condition of the patient, about the plan of therapy, and possibly about prognosis.

It is quite understandable that this technic would develop differently in the hands of different teachers. Even if the teaching physician understands perfectly his primary responsibility of helping his patient, as a teacher he also has another task, namely, to use his patient as "teaching material" for his students. These responsibilities are not wholly antagonistic, for undoubtedly the student by his examinations and laboratory investigations not only furnishes valuable concrete contributions to the "work-up" of the case but by his questions and comments stimulates his teacher to a more critical and searching appraisal of clinical data. Thus, the presence of a student "on the case" is often an asset.

of prime value in ascertaining knowledge of disease, the high position in which teaching hospitals are held in lay and professional regard is testimony to this fact.

However, this knowledge of disease which the student assists in acquiring and assembling is not always handled in such a way as to bring optimal benefit to the subject, too much is not known of the disease but too little is known of the patient and too little attention is given to satisfactory relating of patient and medical knowledge. The second responsibility of the clinical teacher, i. e., the use of the patient as teaching material, may quite obviously bring danger to the patient as well as influence harmfully the attitude of the physician-to-be, although the pedagogic procedure is an absolute necessity from the point of view of teaching the student it can be considered also as a necessary evil both from the point of view of the patient and from the point of view of the physician who in the first instance wants to help the patient and to avoid everything that might damage him.

The idea has been developing in medicine that physicians are not treating diseases but are dealing with diseased human beings. Doubtless considerable progress has been made along this line and the fundamental idea seems to be well understood, but in clinical pedagogy how is it possible to reconcile one's understanding of the patient as a human being with the teaching necessity of using him as "material"?

It is our impression that in teaching hospitals and dispensaries the majority of the patients concerned lend themselves to the teaching of their physicians with remarkable good will and grace. It is relatively rare that a patient rejects the suggestion of being shown and examined and possibly for a time treated under guidance by a student. This attitude, we want to stress, increases the physician's obligation when doing any bedside teaching to find the right way to satisfy both the students' needs and his patients' feelings.

In his preclinical years the student has been used to dealing with "material" of different kinds in a very free manner, he had the opportunity to discuss everything perfectly freely with his teacher individually or in a group regardless of the physical presence of the "material" concerned. When he comes into his clinical years he is confronted with a new situation. The connecting link between him and his teacher is no longer a guinea-pig, an anatomic or pathologic specimen, or a biochemical reaction, but another human being. The student is likely to throw himself on the patient with an eagerness similar to that which he displayed when taking hold of preclinical "material." Even if it is assumed that a goodly number of students bring with them to their clinical years sympathetic understanding and much tact the idea cannot be avoided that the development of their "bedside manners" will greatly depend on the bedside manners of their clinical teachers.

We have had the experience that some clinical teachers with the best of intentions, of course, are not dealing in the most desirable way with their patients when they are examining them in the presence of students. We have noted that for instance, the subject of blood pressure is freely discussed at the patient's bedside and have seen patients who heretofore were ignorant of their own blood pressure and of the conception of blood pressure for that matter worried for weeks about their alleged hypertension so that it became almost necessary to institute special psychotherapy. A remark may be made by the teacher or by the student

like this "I can feel his kidney." Even though it is possible afterward to explain to the patient that in certain lean people the normal kidney can be palpated, such a remark is, to say the least, entirely superfluous. But such mishaps are almost innocent in comparison with remarks about possible tuberculosis or tumor. Such remarks, especially if they are made with the well known "objectivity as to material," can hit the patient like a thunderbolt and can break down his morale and hope of recovery.⁵

A patient in a condition of anxious depression had a slight swelling of her finger on which she wore her wedding ring. A young doctor remarked that "the best thing would be to cut it off," meaning, of course, the ring. The patient, however, thinking he meant her finger, spent some days in agony lest the finger be amputated.

All manner of highly undesirable remarks and discussions are likely to occur if charts, specimens and roentgenograms are indiscriminately exhibited during bedside teaching. One has to realize that the patients or at least many patients, are under emotional stress in this situation and only too apt to listen anxiously and to interpret wrongly what they hear. It is, of course, another matter if the experienced physician purposely gives a patient, of whose sensible and understanding attitude he is sure, some appropriate information on, say, his temperature or his anatomy and physiology.

We think that it cannot be emphasized enough that the patient offers himself, in a sense, as a sacrifice when he lends himself to bedside teaching and that he is entitled to be dealt with in the gentlest and most considerate way. Whether or not he appears to be a sensitive person does not matter at all. Every patient ought to be treated as if he were sensitive, and every remark that might hurt a patient's sensitivity must needs be avoided if physicians want to carry on and further develop bedside teaching.

It is our opinion that the student must be made familiar with the considerate attitude toward a patient that is expected of him at a very early period of training. It is desirable to acquaint the student with this attitude before he goes into his clinical years. For this reason psychiatrists for years have urged that course be offered in introductory psychiatry or medical psychology or whatever one wants to call them—courses in which at the outset lectures are given to the student explaining what is understood under personality and emphasizing the necessity of dealing with patient assigned to him as human beings, forgetting that there ever existed the conception "clinical material." In such a course the first periods may be devoted to theoretical topics, but later the presentation of persons should be introduced. It is practical and promising first to show healthy and normal human beings, always having in mind, however, the fundamental idea that what must be brought home is the fact that the demonstrated person

⁵ Although we are principally concerned in this paper with situations involving student teaching we wish to inveigh again at this point under any circumstances of all considered tactless discussions of a patient's problems in his hearing. For example a thoughtless remark and physician were discussing the examination just made of a 4 year old child. The boy looked up from his supine position and with a sobbing voice said "I know what you are saying and it worries me." A loud voice in discussion in a room below that of the patient or heard whisperings outside a door may bring needless suffering. To practice in pediatric bedside teaching of discussions carried on in the hearing of very young children is usually considered harmful. It is said, "The child cannot understand what we are saying." It is not the fact, however, children often understand spoken language more adequately than adults imagine. But even if the child is not clearly understood what of the frown or shoulder shrug or face or ill timed smile or laugh? This sign language carries a message no less fraught with potentialities than the most direct communication with an adult.

is a human individual, a fact which, of course, implies that the subject is an individual belonging to a group, or rather to various groups small and large, to a family, to a community, and so on. It is necessary to develop the idea in front of the student that the patient has some sort of personality makeup which has been and still is developing in a certain social and cultural milieu. Later in the course, slightly "abnormal" and then seriously sick personalities may be demonstrated, after the demonstration, the patient's difficulties should be discussed in as detailed a way as possible, it being shown how they were bound to develop under the given circumstances and, further, how problems of disease entered into the picture and were dealt with by this specific human being. Problems of therapy may be left out in such a course altogether, but it may be useful in one or two of the later discussions to make reference to treatment and to expound in a very general way modern trends in that subject.

Needless to say, in such a course and ever after, discussion of the patient's problems in the presence of the patient himself ought to be scrupulously avoided. For a time it is necessary to call the attention of the students to this avoidance, but later it should become "second nature" to students and instructors alike. It is very easy in any clinical demonstration to let the patient leave the room before the teacher starts his discussion. It is equally easy for the teacher to leave the patient's bedside with his students after the examination has been accomplished and before he begins to discuss the patient with the student group. In every teaching hospital there are rooms to which the teacher may retire with his students and where he can discuss pathology and therapy to his heart's desire without hurting the feelings or threatening the interests of his patients.

One might say that most patients are naturally anxious to learn about the physician's conclusions as soon as possible. This is doubtless true and it belongs to the responsibility of the physician to give his patient all the information to which he is entitled. But this, in general, should not be done in the presence of other people. The relationship between patient and physician is a very subtle one, so subtle indeed that it can be disturbed by an inconsiderate word, which is much more difficult to avoid in the presence of a third party and which is more difficult to correct than when the patient and his physician work only with each other. It is necessary that in the discussions following the bedside teaching the student should be told how to approach the problem "What am I to say to my patient?" We realize that part of our students will learn this very fast. We realize, furthermore, that another part may never learn it satisfactorily. We trust, however, that if the clinical teachers are entirely aware of what they are doing, our students will acquire better "bedside manners" and our patients will profit by such an improvement.

We are not unmindful of the fact that nowadays when the newspapers print daily some sensational discussion of diseases and their treatment, and when the patients come for our help filled with "enlightenment" obtained from this and similar sources, the physician is often placed in a difficult position. However, we do not think that this position is too difficult to be mastered if we ourselves are conscious of our profound obligations toward those human beings who come to us as patients, and if we incessantly preach these obligations to those who will be our colleagues and successors in the profession.

TOM D. SPIES, M.D.

CINCINNATI

For this consideration we do not know whether the mouth lesions here to be described should be classed as complications of or as an essential part of the complex disease caused by the chronic use of alcohol. We know they occur very often and are the forerunner of a serious condition known as alcoholic pellagra, which is probably a deficiency disease. In that sense the mouth lesions are a complication. If, however, it is ultimately learned that all the important lesions of chronic alcoholism are due to the fact that the alcoholic addict substitutes "drink" for food or that alcohol so deranges his digestion that he cannot utilize food, either one or both devices may be present, then we should rightly say that these mouth lesions are an essential part of a complex deficiency disease known as chronic alcoholism.

No one will know the importance of deficiencies in the pathology of chronic alcoholism until early diagnosis is made and adequate treatment applied in a large group of cases. For that reason we present our observations on a series of patients so studied. The case material of this report is a group of seventy-three patients from Lakeside Hospital and the Cleveland City Hospital described¹ in 1933 as alcoholic pellagrins, and a second series of 125 cases² of pellagra, 95 per cent of which were known as chronic alcoholic addicts. In the first series 88 per cent had mouth lesions, in the second series, more than 50 per cent. The same lesions we have also seen in a large percentage of patients treated in the Cincinnati General Hospital, Division of Psychiatry, for delirium tremens, some of whom must be classed as mild pellagrins.

Because of the prevalence of these lesions, which can easily be found if looked for, we suggest that any one addicted to alcohol who comes complaining of weight loss, poor appetite or weakness should be so examined.

The tongue, lips and buccal membranes, gums and palate are all concerned and the term stomatitis covers the condition generally.

As to glossitis, the tongue becomes slightly swollen as evidenced at first by an increase in size and later by teeth impressions at the sides and tip (fig 1). This

Fig. 1.—Teeth impressions at sides and tip of tongue due to swelling.

2. Spies, T. D. The Treatment of Pellagra. *J. A. M. A.* 104: 1377 (April 20) 1935.

swelling is almost always associated with bright red discoloration or exaggeration of the normal color. It is remarkable how little of coating there may be, even though the patient eats poorly. As the process extends, more and more of the tongue is involved and there is an increase in the intensity of the red discoloration and in the swelling. If treatment is not given, ulcers may appear along the sides and tip rarely on top (fig 2).

Fig 2—Early ulceration of the tongue.

Often the tongue becomes semianesthetic, though occasionally it is hypersensitive. There is not so much complaint of sore tongue in the delirium tremens group as among the outspoken pellagrins.

Stomatitis follows a course similar to that of glossitis. The gums and mucous membranes become deeply red-

tender (fig 3). If left untreated, the process extends and often involves large areas, and here and there may appear ulceration of a mild form. The diffuse redness of buccal membranes and soft palate suggests that seen at the onset of influenza, except that there may be no conjunctivitis and no rhinitis. The gums are quite like any form of severe "pyorrhea" and the Vincent's organism is easily demonstrated. A publication by one of us (T D S) describing the relation of vitamin deficiency to Vincent's infection is soon to appear.

These lesions respond almost immediately to adequate specific therapy if such treatment is started early in the course of the disease. The methods of treatment which we found to be most efficacious in the treatment of pellagra have likewise proved to be beneficial in treating the glossitis and stomatitis complicating chronic alcoholism. These methods consist in the administration of a well balanced, highly nutritious diet of at least 4,000 calories a day, supplemented by 25 Gm of yeast or liver extract three times a day. Wheat germ administered in amounts of 50 Gm four times a day as a supplement to the diet is also very beneficial. Response to such methods of treatment is dramatic, marked improvement occurs in from twenty-four to thirty-six hours, and within a few days the tongue and mucous membranes have changed from dark red to grayish pink and have returned to their normal size.

Whether or not the glossitis and stomatitis observed in the chronic alcoholic addict and characterized by reddening, swelling and ulcerations of the tongue, gums

and oral mucous membranes would eventually develop into a condition recognizable as true pellagra is not pertinent to the welfare of the patient. The important thing is that the physician be constantly on the watch for such oral changes so that proper treatment may be administered in time to prevent the development of more serious conditions.

SUMMARY

In a series of over 200 patients suffering from chronic alcoholism and pellagra, approximately 60 per cent were found to have specific lesions of the mouth and tongue. Early treatment consisting of a nutritious diet of 4,000 calories and 75 Gm of yeast or liver extract daily caused the lesions to disappear. Such lesions frequently precede alcoholic pellagra and are considered to be manifestations of a serious deficiency state.

THE ETIOLOGY OF POLYNEURITIS IN THE ALCOHOL ADDICT

NORMAN JOLLIFFE, MD

AND

C N COLBERT, MD

NEW YORK

That vitamin deficiency may be an etiologic factor in the development of polyneuritis in the alcohol addict was first mentioned on theoretical grounds by Shattuck¹ in 1928 and Minot² in 1929. The work of Wechsler,³ Minot, Strauss and Cobb,⁴ and Meyer⁵ indicates that the alcohol addict with polyneuritis has, as a rule, a qualitatively inadequate intake of food and vitamins and that the clinical manifestations and pathologic observations of beriberi and "alcoholic" polyneuritis are similar. These authors suggested, therefore, that vitamin B deficiency may be the decisive factor in producing polyneuritis in alcohol addicts. Strauss⁶ and Blankenhorn and Spies⁷ showed that patients having "alcoholic" polyneuritis improved if treated with a diet rich in all vitamins, supplemented by oral and parenteral administration of preparations rich in vitamin B, even while they were given from a pint to a quart of blended whisky daily. Strauss concluded that ingestion of whisky has no demonstrable toxic effect on the peripheral nerves.

Cowgill⁸ has shown that the vitamin B (B_1) requirement of man can be estimated by the formula

$$\frac{\text{Vitamin B mg equivalent}}{\text{Calories}} = 0.0000284 \text{ weight in grams}$$

This formula indicates that the vitamin B requirement of man is proportional to both caloric intake and body weight. From the nature of the equation, the expression $\frac{\text{Vitamin B mg equivalent}}{\text{Calories}}$ (hereafter referred to as the

vitamin/calory ratio) may be used as a quantitative expression, by reference to Congill's prediction chart,⁹ of the adequacy or inadequacy of the vitamin B content of the diet of an individual of known weight. Using this method in a recent study, we⁹ estimated the vitamin/calory content of the diets of forty-two alcohol addicts who gave reliable histories. By including in the estimation of the vitamin/calory ratio the first 1,600 calories derived from alcohol we demonstrated (1) that the diets of alcohol addicts with polyneuritis failed over an effective period of time to contain adequate quantities of vitamin B as compared with the predicted requirement of each patient, (2) that the diets of alcohol addicts without polyneuritis, though the addiction was of long duration, contained adequate quantities of vitamin B as compared with the predicted requirement, (3) that certain subjects without polyneuritis consumed enough alcohol over an adequate period of time to cause peripheral nerve involvement if alcohol per se was its cause. We present in this study additional evidence, in the form of therapeutic results, that vitamin B deficiency is the cause of polyneuritis in the alcohol addict. In presenting this evidence we are aware of the hazard of interpreting therapeutic results without a definite objective yardstick. Moreover, peripheral neuritis is a chronic disease, subject to wide variations in the degree of involvement, in which therapy effects complete cure only after a long period of time, with an occasional complete failure.¹⁰ These subjects frequently have a multiple rather than a single deficiency, and in some the pathologic changes may be so far advanced as to be irreversible. Even in experimental animals, maintained with a diet deficient only in vitamin B, therapy which is usually curative may fail completely.⁸ However, by the alternate case method of study we have obtained three groups of subjects of about equal severity of peripheral nerve involvement in whom we believe the therapeutic results may be compared.

METHODS OF STUDY

The alcohol addicts selected for this study had polyneuritis, as evidenced by symmetrical sensory changes in the peripheral nerve distribution of the lower extremities and as a rule by changes in the deep tendon reflexes. Patients having complications likely to increase the vitamin B requirement, or likely to prevent absorption from the gastro-intestinal tract or utilization of vitamins (pneumonia, tuberculosis, hyperthyroidism, delirium, vomiting, diarrhea, pellagra, clinical icterus, ascites), were excluded from this study. A palpable liver, dependent edema, low grade fever, achlorhydria, anemia, anorexia or a psychosis not associated with delirium did not cause exclusion. The selected patients were placed in rotation into groups A, B and C until twenty-three subjects were studied, then five successive patients were placed in group C, making a total of twenty-eight subjects. Certain subjects in groups A and C, following observation in their respective groups, received treatment designed to test a therapeutic agent. All subjects were given physical therapy, and symptomatic treatment was given as occasion required. Observations on changes in the neurologic status were made by the same observer at weekly inter-

vals, and in certain subjects daily. Because of variations in interpreting hyperactivity or sluggishness of tendon reflexes, they are reported only as being present or absent. For similar reasons, changes in skin sensitivity are reported as to extent but not degree. Changes in vibratory sense are reported as to extent of complete loss.

Group A. The seven patients in this group were given a basal diet¹¹ estimated to contain 2,190 calories and 3,680 mg equivalent (736 Sherman units) of vitamin B. The vitamin/calory ratio of this diet is 1.7, which is of borderline adequacy for subjects weighing from 58 to 63 Kg. Subject 5 weighed 56 Kg, and the remaining subjects weighed 58 Kg or more. Subjects 3, 4 and 6 received daily 18 Gm of vegex¹² which had been autoclaved on two successive days for four hours at 20 pounds pressure. This treatment, as shown by growth tests on rats, destroys the antineuritic vitamin B.

Group B. The eight patients in this group received the same basal diet as those in group A, but in addition they were given 18 Gm of unheated vegex daily. The vegex contains about 225 mg equivalent (45 Sherman units) of vitamin B per gram. This added 4,050 mg equivalent of vitamin B to the basal diet, making the vitamin/calory ratio 3.6, which is double the vitamin B requirement of a subject weighing 64 Kg.

Group C. The thirteen patients in this group received a vitamin rich diet estimated to contain 3,100 calories and 17,250 mg equivalent of vitamin B, resulting in a vitamin/calory ratio of 5.5. To this diet was added 18 Gm of vegex daily, bringing the vitamin/calory ratio up to 6.8. This ratio is almost twice that received by subjects in group B, and four times that received by subjects in group A.

RESULTS

Observations on the objective neurologic signs of peripheral nerve involvement in the seven patients in group A, and the results of maintaining them with a diet containing a vitamin/calory ratio of 1.7, are summarized in table 1. No patient showed objective signs of motor or sensory improvement. Subject 6, who weighed 90 Kg, developed a bilateral foot drop after twenty-nine days. Subjects 2, 3 and 4 showed advancement in the sensory abnormalities at the end of twenty-eight, thirty-three and twenty-seven days respectively of observation. Subjects 3, 4 and 6 received autoclaved vegex in addition to the basal diet, but, like the subjects who did not receive this supplement, they failed to improve.

Observations on the eight subjects in group B, maintained with the identical diet as the subjects in group A but with a supplement of 18 Gm of (unheated) vegex daily, are summarized in table 2. No subject became worse. Subject 9 failed to show either motor or sensory improvement after forty-four days. In three subjects (8, 11 and 15) sensory improvement was observed by the twenty-first day, in the remaining four sensory improvement was observed later. Six of the eight subjects in this group showed motor involvement by our criteria. Improvement in the motor phase was observed in three of these by the twenty-first day. In two (subjects 8 and 15) the motor improvement consisted of a return of knee jerks and in the third (subject 11) the bilateral foot drop disappeared. In no subject were

68 are summarized in table 3. No subject became worse. All the subjects in this group showed improvement in the sensory status, eleven of them within twenty-one days, while objective motor improvement was noted in ten subjects, all within twenty-one days. At the beginning of treatment the knee jerks were absent in ten subjects, they appeared in seven within twenty-one days. At the beginning of treatment ankle jerks were absent in all thirteen subjects, they appeared in five within twenty-one days. In the three subjects who showed no motor improvement the ankle jerks remained absent after thirty-eight, forty-eight and thirty-three days and the knee jerks after thirty-eight and thirty-three days of treatment.

Observations on the five subjects originally treated in group A or C but who later received different therapy are summarized in table 4. Subject 6, who grew worse after twenty-nine days in group A on the basal diet supplemented by 18 Gm of autoclaved vegex, was then placed in group C. No improvement was noted by the twenty-first day but by the thirty-fourth day the foot drop and wrist drop had disappeared and biceps jerks returned and sensory improvement was noted.

Subject 5 was treated for thirty-nine days in group A on the basal diet without motor or sensory improvement occurring. She was then given for seventy-two days 10,000 mg equivalent daily of a vitamin B concentrate¹³ by mouth. This supplement brought the vitamin/calory ratio up to 6.5. No objective motor or sensory improvement was observed during this time. A preparation of vitamin B for parenteral administration was not then available.

Subject 7 was treated for seventy-four days in group A on the basal diet without improvement occur-

ring. At this time there were absent ankle jerks, bilateral foot drop, and extreme skin hyperesthesia in the lower extremities. The patient was given by intravenous injection for five consecutive days 10 mg of crystalline vitamin B₁.¹⁴ Within forty-eight hours after 20 mg of crystalline vitamin B₁, the knee jerks had returned, the foot drop disappeared, and the sensory status was strikingly improved. By the sixth day after 50 mg of crystalline vitamin B₁, the patient was able to get out of bed for the first time in eight days. On the ninth day the diet was changed to the vitamin rich diet of those in group C supplemented by 18 G of vegex, but within a week (sixteenth day) the knee jerks had disappeared, the foot drop returned and the sensory abnormalities had recurred, though by no means as severely as previously. Continuing the vitamin rich diet and vegex, 10 mg of crystalline vitamin B₁ was given daily by intravenous injection for two days beginning on the seventeenth day. Dramatic improvement was again noted within forty-eight hours. The patient remained in the hospital seven days more, during which time the improvement was maintained, it has been maintained since then for eight months.

Subject 4 was observed for twenty-seven days in group A with the basal diet and a supplement of 18 G of autoclaved vegex. During this time, sensory abnormalities became worse. The patient was then given by intravenous injection for fourteen consecutive days 10 mg daily of crystalline vitamin B₁. Sensory improvement was noted on the third day. The knee jerks returned on the fourteenth day, and further sensory improvement was noted. The patient was placed on the vitamin rich diet used in group C, and there has been no regression up to the time of this writing twenty days later.

Subject 24 was treated in group C for eighty-two days, with good motor and sensory improvement. The sensory status at this time was normal but the knee and ankle jerks remained absent and the gait was widened base. She was then treated as in group A for 127 days taking an unweighed but vitamin rich diet supplemented by three level teaspoonfuls of vegex (about 18 Gm) daily. The knee and ankle jerks

¹³ Courtesy of Eli Lilly & Co., Indianapolis

On the tenth day, however, the knee jerks were obtained, and they were still present thirty days later at the time of this writing

COMMENT
The etiology of polyneuritis in the alcohol addict is further clarified by the response of the subjects in this study to diets containing various quantities of vitamin B. The subjects in group A who received a diet of borderline adequacy in vitamin B or slightly less than their predicted requirement, depending on their weight, failed to show improvement. In some there was advancement in objective neurologic signs of peripheral nerve involvement. If alcohol per se were the cause of peripheral neuritis, the removal of alcohol from the daily regimen should have resulted in some of the subjects showing improvement during the period of observation, which varied from twenty-seven to seventy-four days. Their failure to improve when alcohol was withdrawn together with the observation of Strauss⁶ and of Blankenhorn and Spies⁷ that "alcoholic" polyneuritis will improve while patients consume from a pint to a quart of whisky daily if the diet is rich in vitamin B and together with the evidence of Jolliffe, Colbert and Joffe⁸ that alcohol addicts who maintain an adequate vitamin/calory ratio do not develop polyneuritis even though they consume large amounts of whisky over many years leads us to believe that alcohol

per se is not the direct cause of a symmetrical peripheral neuritis

In table 5 we have summarized the changes occurring within twenty-one days in the three groups of cases. The subjects in group A, given a basal diet containing a vitamin/calory ratio of 1.7, failed in every instance to show either motor or sensory improvement. The subjects in group B, given the same diet plus a supplement of vegex by mouth sufficient to increase the vitamin/calory ratio to 3.6, showed as a group definite but moderate improvement. The subjects in group C, who received a vitamin rich diet which, supplemented by vegex, contained a vitamin/calory ratio of 6.8, showed more rapid and decided improvement than the subjects in group B. The vitamin B adequacy of the three groups may be stated as follows: group A, borderline; group B, approximately twice the predicted requirement; group C, approximately four times the predicted requirement. The degree of improvement was therefore roughly proportional to the vitamin B intake. The contention that the amount of vitamin B intake decisively governs the degree of improvement is valid in groups A and B. The only difference in the

regimen of these two groups was that subjects in group B were given 18 Gm of vegex daily, while subjects in group A received either autoclaved vegex or no vitamin B supplement. Vegex is a complex preparation of autolyzed brewers' yeast containing, in addition to vitamin B, vitamin G, which now is thought¹⁵ to

15 Burch T W, Gyorgy Paul and Harris L J. The Vitamin B₂ Complex Differentiation of the Antiblacktongue and the P P Factors from Lactoflavin and Vitamin B₂ (So-Called Rat Pellagra Factor) Parts I VI Biochem. J 19 2830 2850 (Dec) 1935

consist of several fractions such as the pellagra preventive factor, the anti-black tongue factor, lactoflavin, and vitamin B₆. In autoclaving this product we may have destroyed or impaired another fraction in addition to vitamin B. It may be suspected that the failure of patients in group A, who received autoclaved vegex, to improve was due to the destruction of this other factor, and that the response of the subjects in group B was due to its presence in the unheated vegex. That this is not the true explanation is shown by the course of subjects 4 and 7, who responded with improvement when the basal diet, or the basal diet plus autoclaved vegex, was supplemented by crystalline vitamin B₁. If the improvement of patients in group B were due to another fraction than vitamin B, it would not have occurred in subjects 4 and 7. The failure of subject 7 (table 4) to maintain the improvement that occurred after 50 mg of crystalline vitamin B₁ was given with the basal diet, and her maintaining the improvement that occurred after 20 mg of crystalline vitamin B₁ was given with the vitamin rich diet supplemented by vegex, and the permanent improvement of subject 4 after 140 mg of crystalline vitamin B₁ was administered with the basal diet supplemented by autoclaved vegex suggests that some factor may be present in both autoclaved and unheated vegex which in itself is not curative but which, when present with adequate

experiments. When separate fractions of the vitamin B complex are added to a diet lacking in the entire vitamin B complex, there occurs a temporary increment in weight which is not maintained until all necessary factors are included in the diet.

It is difficult to account for the failure of subject 7 to maintain the improvement produced by 50 mg of crystalline vitamin B₁ administered by parenteral injection. Before and during this therapy the patient received the basal diet. From the day following the last administration of crystalline vitamin B₁ she was given the vitamin rich diet supplemented by vegex. In spite of this, regression occurred within a week. To the vitamin rich diet plus vegex we then added within two days 20 mg of crystalline vitamin B₁. The prompt improvement which followed this time has been maintained over a period of eight months of observation. Our previous suggestion that some factor may be present in both autoclaved and unheated vegex which while not curative in itself, augments the curative action of vitamin B may be the correct explanation of the relapse. On the other hand, the explanation may be a temporary failure of this patient to absorb the vitamin B given by mouth during the week between the end of the first and the beginning of the second period of crystalline vitamin B₁ therapy.

The failure of subject 5 to respond by improvement after seventy-two days of treatment with the basal diet supplemented by the oral administration of 10,000 mg equivalent of a vitamin B concentrate does not mean that this preparation is without value. We have treated two subjects¹⁷ having gestational polyneuritis, also due to vitamin B deficiency,¹⁸ with this preparation, with excellent results. Furthermore, subject 5 had a very severe polyneuritis and may represent a group of subjects in whom the pathologic changes have advanced so far as to be irreversible. Another explanation may be that her polyneuritis was on a different etiologic basis, a possibility to which we have referred in a previous study.⁹

Failure of the tendon reflexes to return after a few weeks or months of vitamin B therapy by mouth does not necessarily indicate that they will be permanently absent. The knee jerks in subject 24, after 221 days of known absence, returned when the vitamin rich diet was supplemented for nine successive days by the daily intravenous administration of 10 mg of crystalline vitamin B₁.

SUMMARY

We have observed twenty-eight alcohol addicts having uncomplicated polyneuritis who were given diet containing slightly inadequate or barely adequate quantities of vitamin B, or diets containing either approximately two times or four times the estimated vitamin B requirement. Those receiving borderline amounts of vitamin B showed no improvement in the objective signs of peripheral neuritis over a period of a month. Two of these subjects were then given crystalline vitamin B₁ by intravenous injection with dramatic response in one and a good response in the other. Subject treated with a vitamin B intake approximately twice their predicted requirement showed improvement but not as rapidly or in equal degree as those receiving four times their vitamin B requirement. We have discussed the relation of alcohol to the etiology of polyneuritis and the possibility of a fraction in the vitamin

TABLE 5—Summary of Changes in Objective Neurologic Signs of Peripheral Nerve Involvement in Groups A, B, and C Within Twenty-One Days

| | No of Cases | Vitamin/Calory Ratio of Diet | Worse | | Unimproved | | Improved | |
|---------|-------------|------------------------------|-------|---------|------------|---------|----------|---------|
| | | | Motor | Sensory | Motor | Sensory | Motor | Sensory |
| Group A | 7 | 1.7 | 1 | 3 | 6 | 4 | 0 | 0 |
| Group B | 8 | 3.6 | 0 | 0 | 3 | 1 | 3 | 7 |
| Group C | 13 | 6.8 | 0 | 0 | 3 | 2 | 10 | 11 |

amounts of vitamin B, augments the curative properties of the latter.

Patients in group C, whose vitamin B intake was approximately four times their requirement, showed more decided improvement than those in group B, who received only two times their vitamin B requirement. For example, in patients in group B, absent ankle jerks were not observed to return within twenty-one days, while in patients in group C, absent ankle jerks returned within twenty-one days in five of the thirteen subjects.

While we are justified in attributing the better response of patients in group B than those in group A to vitamin B, the still better response of the patients in group C cannot with certainty be attributed solely to the increase in vitamin B. The diet in group C contained 50 per cent more calories and an equal increase in protein. Vitamins A, D and C were also present in larger amounts than in the diet of groups A and B. When we increased the vitamin B content from around 3,000 mg equivalent in the diet of groups A and B to 17,000 mg equivalent in the diet of group C, we also increased other fractions of the vitamin B complex. In this connection the observation of Elsom¹⁹ is significant. Vitamin fractions contained in yeast were necessary in addition to preparations of vitamin B₁ and B₂ for complete relief from the changes which accompanied deficiency in the vitamin B complex. This clinical observation is confirmed by deficiency

B complex other than vitamin B itself augmenting the action of vitamin B on polyneuritis in the alcohol addict. We conclude that

1 Alcohol per se is not the cause of polyneuritis in the alcohol addict

2 Vitamin B deficiency is a cause of polyneuritis in the alcohol addict

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs BLANKENHORN AND SPIES AND
DRs JOLLIFFE AND COLBERT

DR. H. B. MULHOLLAND, University, Va. Until recently the etiology of polyneuritis in chronic alcoholism was thought to be due to the effect of the alcohol on the nervous tissues. The work of Strauss and others demonstrated an improvement in the symptoms and signs of nervous lesions occurring in alcoholic addicts in spite of the continuance of an average alcohol intake, when the patients were put on adequate diets. This is further amplified by these authors, who in a new and ingenious method of attack have apparently shown that vitamin B is quantitatively concerned in the etiology and cure of this condition. I am interested in the fact that in order to obtain satisfactory results it is often necessary to give patients many times the average requirement of vitamin B. This fact has been shown to be true in other deficiency syndromes. It is therefore possible that the factors of absorption and storage may play an important part in the development of deficiency states. An example is the case which responded to the intravenous administration of crystalline vitamin B₁ after not having shown any improvement on a very high intake by mouth. A case of chronic alcoholism recently observed in our hospital presented the picture of macrocytic anemia and symptoms of peripheral neuritis. The reflex changes were of a minor degree, and the lesions cleared up so promptly on the administration of liver and adequate diet that I believe this is another evidence of a deficiency neuritis complicating pernicious anemia in a chronic alcoholic patient. I wonder whether the authors have observed any such cases with macrocytic anemias in their series. The whole question of peripheral neuritis should be reopened and resurveyed in the light of recent work for instance, peripheral neuritis complicating diabetes and other diseases. The importance of mouth lesions occurring in deficiency diseases, particularly those associated with the vitamin B complex, has just recently been recognized. Indeed, in pellagra these lesions may be used as a guide to the efficacy of therapy. The authors have called attention to a common condition occurring in chronic alcoholic patients which if treated by adequate dietary measures, may preclude the advent of more serious deficiency states. The lesions described are certainly rather typical of pellagra as seen in the nonalcoholic patient. These two papers seem to carry important therapeutic implications in the treatment of chronic alcoholism.

DR. TOM SPIES, Cincinnati. I cannot agree with Drs. Jolliffe and Colbert that their conclusions concerning vitamin B have been established. The present status can be approached best from a historical standpoint. Lettsom in 1787 first described alcoholic polyneuritis and attributed it to a neurotoxic effect of the alcohol. This belief was not seriously questioned until 1928. The first controlled information occurred by accident when Dr. De Wolf and I were studying the relationship between chronic alcoholism and the development of alcoholic pellagra. We observed that the neuritis did not progress in patients taking large quantities of whiskey if they ate large amounts of food. Dr. Strauss using the same method, showed subsequently that alcoholic neuritis unaccompanied by pellagra responded in a similar manner. Later, Dr. Blankenhorn and I treated fifty cases of alcohol polyneuritis, some with and some without pellagra. Their cure was reported in May 1935. At that time we stressed the therapeutic value of a high caloric well balanced diet supplemented by large amounts of the vitamin B complex in the form of yeast, liver extract or wheat germ. Drs. Jolliffe and Colbert added the next step by attempting to establish a quantitative relationship between the number of calories and the amount of the vitamin B complex in the diets of these people. Such a relationship

had already been established in animals by Dr. Cowgill. In my opinion, Drs. Jolliffe and Colbert have not proved their point. First, their method of calculating the dietary intake is open to criticism. They failed to consider that the alcoholic addict is interested only in drink and will lie and throw food away to avoid eating. Second, they take alcohol away from people who are accustomed to large amounts. Third, they give these patients physical therapy, which in itself sometimes aids in the treatment of polyneuritis. Fourth, the studies are sufficiently long to allow a possible deficiency of certain other portions of the diet to arise. I believe that vitamin B₁ has something to do with alcoholic polyneuritis, but I also feel that it is not the only factor involved. From my studies it seems that the more restricted diets require larger supplements of the vitamin. The contribution of Drs. Jolliffe and Colbert is significant and I am sure that they will soon put the study on a more scientific basis.

DR. NORMAN JOLLIFFE, New York. In answer to Dr. Mulholland's question concerning macrocytic anemias in these patients, we found in 100 consecutive cases of polyneuritis that about one third showed a macrocytic anemia. As to the points made by Dr. Spies. We are aware that alcohol addicts as a group give unreliable histories, that they are liars, and that they frequently have memory impairment. For this reason I wish to reemphasize our method of judging the accuracy of histories. We chose patients that seemed to us likely to give a reliable history, and then only about one in ten would give us the same history on several successive days. If the history of those who did this could be confirmed by relatives or friends, we would accept that history as true. If our error in estimating the diet was as great as 50 per cent, in only one subject would the vitamin B intake be changed sufficiently to be an exception to our conclusions. As to physical therapy, all three groups received it, and this factor, if it played a curative role, was constant. The diet may be restricted, as Dr. Spies has brought out, so much that even crystalline vitamin B₁ will not cause a response. That was shown in one of our patients (case 7). This patient for seventy-four days was given the basal diet. Fifty milligrams of crystalline vitamin B₁ caused only a temporary though dramatic improvement. But 20 mg. of crystalline vitamin B₁ given to the same patient while on a vitamin rich diet was followed by permanent improvement. Another subject (case 4) who received the basal diet plus autoclaved vegex responded permanently following crystalline B₁. This leads us to believe, as Dr. Spies suggested, that other factors present in the B complex influence the curative response to crystalline B₁. This phenomenon occurs in the experimental animal that is deprived of the entire vitamin B complex. When separate fractions of the B complex are added, only a temporary response occurs. Add a second fraction, and again a temporary response follows. A permanent response is not established until all fractions of the vitamin B complex are added to the diet. I believe this is the explanation for the failure of crystalline vitamin B₁ to maintain a permanent response in subject 7 on the incomplete diet.

DR. M. A. BLANKENHORN, Cincinnati. I can construe Dr. Mulholland's discussion as a question directed to our paper about macrocytic anemia and answer it with practically the same answer that Dr. Jolliffe does, that is to say among our patients that were reported as having pellagra, a large number were found to have macrocytic anemia. I am grateful to Dr. Mulholland for making the statement that these mouth lesions in the condition we have described here greatly resemble the pellagra of the South. In presenting this question of sore mouth in chronic alcoholism, we have avoided almost too carefully the word 'pellagra' because of the psychology of medical minds. When we describe the condition as pellagra, the doctors of the North will say 'Pellagra is a disease of the South and we do not have it in this community and there is no use looking for it.' When we speak of this disease in the South the doctors say 'That is alcoholism, and it is quite different from the pellagra we have in the South.' We welcome the opinion, therefore, that the two conditions are identical. I will close by reiterating the point emphasized yesterday by Dr. Carlson that the early recognition of deficiency states is not scientific and is still in the realm of the practicing physician who sees and looks for minutiae.

sistently showing a hearing loss then receive a special examination of nose, throat and ears by the school medical inspector to eliminate impacted cerumen. A further check on hearing is made with the 2-A audiometer through cooperation with the Central Institute for the Deaf in St. Louis. The audiograms of these tests are filed with the school records and compared with subsequent audiograms. Parents are notified of the hearing loss and advised to consult an otologist for correction when possible. Meanwhile lip reading instructions are begun by teachers trained at the Central Institute for the Deaf of St. Louis.

After one or two years of such instruction, remarkable results were noticed in this group of children. The class room teachers and principals stated that the children were more attentive and had improved in reading,

the ability and progress of the child. A child's educational age should show a gain of at least twelve months in a year's time.

C A, or chronological age, is determined from the birth date. It automatically increases twelve months in a year.

I Q is the intelligence quotient, a ratio of the chronological age to the mental age. In normal children the intelligence quotient remains fairly constant throughout school life. A variation of from 5 to 10 points may be encountered. In cases in which no data are supplied, school records were incomplete.

The intelligence quotients prior to instruction in lip reading are generally lower in table 1 than in table 2, since the deafness in this first group was of longer duration.

in other subjects and, no less important, in behavior. Teachers' marks showed an advance in a majority of the cases, a rather significant fact, since previous to lip reading training 37.5 per cent of these children had been retained in the same grade one or more years, and 31.2 per cent were conditioned.

TABLE 3—A Group of Seventeen Hard of Hearing Children Taking Lip Reading and Sixteen Hard of Hearing Children Not Taking Lip Reading

| | 0 | 0 | 1 | 6.2 |

The accompanying tables are a comparison of a hard of hearing group of children who were instructed in lip reading, with a hard of hearing group who refused lip reading owing to lack of parental cooperation or to unwarranted prejudice or advice.

E A, or educational age, is the figure derived from a composite of subject ages on the Stanford achievement tests. It is probably the best measurement of

CONCLUSION

1 The education of the unassisted hard of hearing child is an interrupted learning, an imperfect acquisition of knowledge.

2 The hard of hearing child should not be segregated from the public school class room, but lip reading should be a part of the curriculum.

3 The hard of hearing child in a majority of cases has a low intelligence quotient because of lack of educational experience and not because of deficient mentality.

4 Lip reading was given in the public schools of Webster Groves, St. Louis County, to a group of hard of hearing children. After from one to three years 47 per cent showed an increase in their intelligence quotient, 41.1 per cent showed no change, and 11.7 per cent showed a drop in their intelligence quotient. In 76.4 per cent definite class room improvement was made, and all showed marked betterment in behaviorism.

5 In contrast, another group of hard of hearing children who refused lip reading showed no increase in their intelligence quotient during the same period, but 75 per cent showed a drop, only 18.7 per cent made class room improvement, and all were character problems.

COMMENT

I have tried by collecting these numerical data and by watching the change in this group of children for three or four years to establish an interest in the need for lip reading in the public schools. Its purpose will certainly be a benefit to the child himself, and secondarily, no less important, to the community. The cost of lip reading should not be considered, since each repeater is an expense of from \$80 to \$100 a year to a board of education. Therefore it is obvious that it will not take very many repeaters made into nonrepeaters to cover not only the cost of lip reading but very likely the cost of the entire school health program.

639 Lee Avenue

ABSTRACT OF DISCUSSION

DR. HORACE NEWHART, Minneapolis. The otologist has long regarded the pediatrician as his closest ally in promoting deafness prevention and amelioration, because of his success in reducing the incidence of the diseases of childhood that cause impairment of hearing. I would emphasize two points related to this subject. The first is the importance of the early discovery of the potentially deafened child, who is most easily overlooked and neglected. The obviously hard of hearing receive attention as a matter of course. The young child having a slight but significant hearing impairment, which is often the cause of retardation, a speech defect, an inferiority complex or even unusual behavior is frequently overlooked by both parents and teachers. Only recently has the urgent need of discovering his defect in time to give him the benefit of early medical and educational corrective measures been realized. This has been made possible by the incorporation of the periodic testing of the hearing acuity by means of the audiometer in the school health program. In several hundred communities this has been undertaken with very satisfactory results. In Minneapolis where the tests have been made as a routine during the past nine years there has been noted a drop in the incidence of a significant hearing loss among the school population from 8 per cent to 4 per cent. This, we believe, is due largely to a growing ear-consciousness among parents. A second point to emphasize is the need of early detection of a severely handicapping hearing loss in the infant and the preschool child because of the educational problem involved. Here the physician carries a large responsibility. A survey of pupils in schools for the deaf in Minnesota by audiometric tests showed that a surprising number had residual hearing of such a degree that with early discovery and the help of a modern hearing aid they might have received their education in their home communities with normal hearing children and avoided the speech defects which made necessary their admission to special schools. Infants and young children who do not respond to the cochleo-palpebral test are mouth breathers, have a high palatal arch fail to acquire normal speech, have frequent colds or cervical adenopathy and should receive early otologic scrutiny. Parents of aurally handicapped children may obtain gratuitously helpful advice regarding their home care from our two national organizations for the deaf and hard of hearing—the American Society for the Hard of Hearing and the Volta Bureau both of Washington, D. C.

DR. HORTON R. CASPARIS, Nashville, Tenn. Dr. Hofsommer has brought to us a subject that is important even beyond the specific phase of it that she discussed, namely the difficulties arising out of hardness of hearing. We get children who are not recognized as deaf or hard of hearing who fail and have to turn to other channels because they can't keep up with their colleagues in school and that is difficult enough. But I think she struck a note that is broader and should appeal to pediatricians, namely that the mind must be exercised just as any other part of our body if it is to remain potent to the extent that there is a handicap we don't get the normal flow of physical activities and hence don't maintain the normal development of our mental functions which I think is important. We see it in other phases of handicap than deafness although deafness is a very severe one.

A CHILDREN'S HOSPITAL FOR NEUROLOGIC AND BEHAVIOR DISORDERS

CHARLES BRADLEY, M.D.

EAST PROVIDENCE, R. I.

In spite of an ever widening interest among pediatricians and neuropsychiatrists in the neurologic and behavior disorders of childhood, hospitals adequately equipped for the study and treatment of patients with such conditions are few and far between. The majority of general and children's hospitals, designed primarily for bed patients with acute disorders, are not prepared to go beyond the stage of diagnosis for children with many chronic neurologic complaints and make no pretense of dealing satisfactorily with active ambulatory children whose behavior demands prolonged treatment. A very limited number of psychiatric hospitals have during the past ten years done pioneer service by establishing wards for problem children.¹ However, no hospital planned and equipped especially for the care of children with neurologic and behavior disorders existed until the Emma Pendleton Bradley Home was opened in 1931 at East Providence, R. I. In this paper, I wish to deal briefly with the experiences encountered during the first five years' operation of this unique institution.

GENERAL DESCRIPTION OF THE EMMA PENDLETON BRADLEY HOME

A semirural location was judiciously selected for the site of the project. The hospital itself occupies an attractive colonial brick building of generous capacity constructed for the purpose and situated in the midst of a 40 acre tract of land largely wooded. Ample playing fields provide natural facilities for children's sports at all seasons, and the absence of close neighbors has eliminated many problems that might arise in congested quarters. Provision for equipment and staff to supply every need of normal child life, as well as the more orthodox clinical and laboratory requirements of a fifty-bed hospital, have made the institution virtually a complete children's community. Special features have been the inclusion of a psychologic laboratory adapted to the investigation of children's problems and a school staffed with specially trained teachers.

The Bradley Home was planned as a hospital for investigation and treatment as opposed to a home for custodial care or a training school. For this reason relatively few children with an obviously hopeless mental defect or with advanced deterioration have been admitted. Initial questions as to what types of patients would appear for treatment in such a hospital may now be answered in the light of considerable experience (table 1). Of 269 patients who have been admitted eighty have presented behavior problems, sixty-four convulsive disorders, forty birth injuries of the central nervous system, thirty-seven mental deficiency and the remainder a variety of disorders such as chorea, specific reading disability, postencephalitic syndrome and mus-

Read before the Section on Nervous and Mental Diseases at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1934.

cular dystrophy All were referred directly by physicians and the majority were patients for whom treatment had been tried unsuccessfully elsewhere

PATIENTS WITH NEUROLOGIC DISEASES

Convulsive Disorders—In reviewing experiences with various types of patients who have come under observation, those with convulsive disorders merit early consideration There are certainly a great many children in all walks of life with convulsive disorders who are being adequately and successfully treated at home without interfering with their schooling or social development There are others, however, for whom therapy is carried out at the expense of many childhood activities, and still others for whom no treatment in the community proves successful It is for patients of the latter two groups that a special children's hospital should have most to offer, and as a matter of fact it is mainly such children who have been treated at the Bradley Home Here hospitalization has not only permitted thorough medical and dietary treatment but has eliminated such precipitating psychogenic factors as may have been present in the patient's home Moreover, it has provided schooling and permitted full participation in other normal activities of childhood during the treatment period

Although the group treated has in general, consisted of patients for whom home treatment had failed, therapeutic results in the hospital have been reasonably encouraging Unfortunately, space does not permit me to present the detailed analysis which is quite necessary for any intelligent statistical discussion of such cases It may be noted in passing, however, that of fifty consecutive children with convulsive disorders for whom hospital treatment was completely carried out, nineteen were entirely free from seizures at the time of discharge, eleven were partially improved, and twenty did not respond to treatment

Cerebral Palsy—Recently the writings of Carlson² Doll³ and others have aroused considerable interest in the treatment and education of the so-called spastic group of birth injured children Patients of this type who are to receive treatment should be selected with great care, as even the most intensive efforts will be relatively unproductive of results if the child suffers from the mental deficiency so common in this group Accurate measurement of the intellectual status is often difficult because of the frequency with which motor and speech disturbances render customary psychometric tests unreliable for these children

In special quarters at the Bradley Home a relatively small group of carefully selected, intelligent children have been given prolonged and comprehensive treatment A wide use of playthings, apparatus and group games supplementing formal physical therapy, school and speech classes have rounded out training not only in motor control and strength but also in social adaptability and in finding satisfactory outlets for self expression The development of self confidence, which accompanies improvement is most important for the future progress of these children It is hard to visualize such thorough treatment being carried out elsewhere than in a specially adapted hospital or school with a staff of nurses selected for their technical skill, patience, optimism and ingenuity While no scale exists by which the relative value of this therapy can

be gaged, the response of these selected patients to such a program is by no means discouraging

Other Chronic Neurologic Disorders—Patients with a variety of other neurologic disorders and myopathies have come under observation, but in no single group large enough to warrant any conclusions from the treatment Research among these patients at the Emma Pendleton Bradley Home is particularly attractive because of the availability of the children for prolonged close observation Whether or not research or treatment is productive of results, the victims of these crippling diseases are meanwhile attending school and enjoying participation in normal childhood activities to a much greater extent than would have been possible at home in the community

BEHAVIOR PROBLEM CHILDREN

In turning to the hospital treatment of children whose difficulties lie in the field of behavior, it is possible to supplement the excellent discussions of Potter,¹ Lurie⁴ and others by presenting a few striking experiences

Value of Environment—There would seem to be little argument that in adequately providing for the care

of ambulatory behavior problem children a great deal of attention should be focused on the environment This consists of far more than merely providing hygienic and attractive living quarters At the Emma Pendleton Bradley Home, where the semirural location at once offers a natural setting for many children's activities, every effort has been made to develop an environment and a program for its use, duplicating the best advantages of the modern community Specifically this has included not only ample provision for all outdoor sports but also complete school facilities with supervised recreation, including scouting activities for both boys and girls, educational trips to nearby points of interest, picnics and camping excursions, the use of a library, woodworking classes, a harmonica band, and many other features The nurses and teachers who have been of most assistance in developing and carrying out such a program have combined the rare endowment of an attractive, unruffled and ingenious personality with extensive experience among normal active children Probably only in the presence of the constructive attitudes that such a staff shows could this program surround the patient with a noninstitutional atmosphere which does not constantly remind him that he is ill, and also renders his transition into and out of the hospital as gentle as possible

⁴ Lurie, L. A. The Mental Approach to the Study of Behavior Disorders of Children. Am J Psychiat 91 1379 (May) 1935

As an aid to psychiatric diagnosis such surroundings provide a natural setting wherein the physician may impartially observe and record the patient's reactions to normal childhood situations. These data may so supplement the physician's history and office contacts as to clarify vividly his understanding of a particular behavior problem. This has been repeatedly demonstrated in actual practice.

That this environment may be of direct therapeutic value by offering security, encouragement and an outlet for self expression to a problem child is suggested in a subsequent analysis of the results of treatment. It also makes another though more intangible contribution to the welfare of every patient regardless of diagnosis. This contribution is to the happiness and social development of the child during the long period he must spend in the hospital. The importance of this is apparent when it is noted that children treated at the Emma Pendleton Bradley Home usually remain in the hospital from six to eighteen months.

Individual Psychotherapy—Even the best environmental adjustment does not preclude the advisability of personal psychotherapy, particularly in cases in which

a rather exhaustive analysis and reconstruction of the patient's personality are indicated. The methods of conversational interview, play analysis and interpretation of artistic production have been freely used as dictated by the characteristics and needs of each child. In treating the child as an inpatient, the physician has been able to make his contacts as frequent and of whatever length he chooses. He has been able to alter at will the child's program of activities. Moreover, the hospital files have provided an accurate and permanent record of the patient's reactions to his treatment. Each of these items presents obvious advantages over what is possible in the average mental health clinic.

Analysis of Cases—In a brief and rather superficial analysis of the patients who have been under treatment for behavior disorders (table 2), it is interesting to note that there were exactly twice as many boys as girls in the group. Out of a total of eighty such children treatment was considered complete in fifty-eight cases. Forty-three of these (74 per cent) were distinctly improved at the time of discharge and fifteen (26 per cent) unimproved. While individual psychotherapy and all other necessary medical treatment was carried out in every case it is the opinion of the medical staff that environmental influences were more often than not the primary beneficial factors for those patients who responded favorably to their stay in the hospital (table 3). Thirty-one of the improved patients

(73 per cent) appeared to owe their improvement primarily to the hospital environment and only twelve (27 per cent) to have owed it to any specific therapy. These results are probably best interpreted as demonstrating what may be accomplished practically by adequate environmental treatment rather than indicating lack of success with personal psychotherapy in such children.

GENERAL COMMENT

In finally scanning the first five years' work of the Emma Pendleton Bradley Home, one is attracted by two or three other salient points.

This experience has lent no support to the theoretical criticism that it is unwise to treat together in a single group children with organic neurologic disorders and those with functional behavior problems only. Neither by imitation nor by irritation have members of either group seriously interfered with their own treatment or that of others. Moreover, the practical convenience of treating together all these patients with obviously similar needs for prolonged therapy, schooling and social development outweighs most theoretical objections to so doing.

Considering the fact that most of the children who were admitted to the hospital represented the more severe types of their particular disorders, it is encouraging that therapeutic results in general have been distinctly favorable.

The beneficial results of a carefully planned environment have been obvious, particularly in the field of behavior disorders. It seems significant that in actually developing this environment many more definite and workable suggestions were received from individuals intimately familiar with healthy children in schools, camps and the like than from those whose training and experience came only from the world of medicine. The implication that many physicians and nurses lack familiarity with the everyday life of active children has led to including prolonged daily contacts with the children in the psychiatric training of all who come to the Emma Pendleton Bradley Home for professional experience.

ABSTRACT OF DISCUSSION

DR. WILLIAM G. LENOX, Boston: I have visited the Bradley Home. I shall, however, speak only of the care of the epileptic patients. I see the Bradley Home against the background of a half million epileptic persons, 10,000 of whom are in colonies, 30,000 in state psychiatric institutions and almost all the rest of the 450,000 without any home to go to in case they need hospital or institutional care. The Bradley Home demonstrates the utility of small units, in which incipient or first stage cases of epilepsy can be given medical care in an environment which approximates that of the home. Certain European countries are far beyond us in providing interested care for early cases. In the second place the home as an experimental station can answer certain questions which need to have convincing answers. Here is a group of mentally normal epileptic patients in a good environment and associated with other patients who are mentally normal. Can Dr. Bradley give convincing evidence that epileptic patients are better as regards their mental health and their personality, than if they had been sent to some state colony or to a psychiatric hospital? On the other hand here is a group of other handicapped patients with a group of epileptic children among them. Can Dr. Bradley give convincing evidence that these other children are not harmed by being in contact with the epileptic children? In his paper he has given his affirmative opinion on these questions and it deserves to be widely respected. Yet I hope that in the course of years he can present statistical evidence that will point the way toward the better handling of the serious problem of the social and institutional care of epileptic patients.

DR. WILLIAM NELSON, St. Louis: I wouldn't limit my dealing with the epileptic children to the purely normal children.

so far as psychic capacity is concerned, because many of the children have certain limitations to mental development. I do not believe that the mental limitation is a handicap to social adjustment of the individual, if society recognizes its responsibility and understands the child. I would not relegate children who have lower levels of mentality to a program of nondevelopment, so far as vocation is concerned. One reason for Dr. Bradley's success in this hospital is his personal relationship with the patient. In any group, if the personal relationship and the actual problem of that individual child are removed so far as relationship to him as an individual is concerned, one is going to defeat the purpose of treatment ultimately. In other words, the temporary adjustment that one gets out of children from mere group treatment, without considering individually one's relationship to that child, is going to defeat one in the long run. If I understood Dr. Bradley correctly, he said that his patients stayed in the hospital from six to eighteen months. I can't conclude, after fourteen years of detailed dealing with these problems, that patients can be considered adjusted after eighteen months. Some of them require further care. In my community the project is carried on somewhat differently, with a shorter stay in the home. We are dealing with the problems that Dr. Bradley suggested here, that other people have failed on, the worst problems in our community. Our idea of keeping them in our home is for the purpose of study and treatment until they can adapt themselves in a more individualized sort of environment.

DR. CHARLES BRADLEY, East Providence, R. I. I wish to thank Dr. Lennox and Dr. Nelson for their discussion. I think our enterprise is too young to draw any conclusions, except that it has worked pretty well so far. As regards the time of treatment for behavior problem children, I like to look at institutional treatment as you do at any hospital treatment. The job of the physician is to get the patient out as soon as possible and, of course, to keep in touch with him and treat him as long as necessary thereafter.

MEDICAL ASPECTS OF ACCIDENT CONTROL

LEVERETT D. BRISTOL, MD, DR.PH
Health Director American Telephone and Telegraph Company
NEW YORK

The prevention and control of accidents depend on the cooperative efforts of public authorities, governmental agencies, industrial management and employees, insurance companies, technical societies, safety engineers, physicians and nurses, as well as on the public in general. Accidents must be combated in the home, in the school, in public places, in travel and in places of work. Administrative, statistical, medical, engineering and educational activities must be covered in any well rounded safety program.

Although much already has been accomplished in safety work, with a marked reduction in the incidence and severity of accidents, much still remains to be done particularly with reference to accidents in the home and in public places and travel. Most of the results during the last two decades in the prevention and control of accidents have been brought about in industries through the development of well organized industrial safety programs. Recent studies made by some of our operating telephone companies in the Bell System indicate that there are three or four times as many accidents to employees while off the job as there are while they are at work, and five or six times as many days lost on account of accidents occurring while away from work as there are while on the job. This emphasizes the need for a far reaching and forward looking program which will concentrate more and more

efforts on public and home safety without a let up in well established industrial safety activities. There is little wisdom in devoting time and money to an industrial safety service within an office or plant and forgetting the fact that most of the accidents to industrial employees now occur while they are away from their regular occupation. While it is realized that management has no supervision over employees while off duty, the industrial safety program so far as its educational aspects are concerned must "carry over" into the homes and leisure time of employees and must become closely integrated with all accident prevention activities of the community.

MEDICAL EXAMINATIONS

The physician's duties and responsibilities in an industrial safety program, while having to do somewhat with various administrative, statistical, inspectional and educational activities, necessarily must be related more specifically to preemployment and periodic physical examinations and to emergency medical and surgical examinations and treatment. While early diagnosis through medical examinations is one of the chief factors in the prevention and control of sickness among workers in industry, the inherent value of the preemployment physical examination so far as the prevention of accidents is concerned is in its potential power to make possible the proper placement of workers from the standpoint of accident hazards and prevent prolonged disability and loss of time from work. Good physical condition, as a rule, means more rapid recovery from accidental injuries, poor physical make up is conducive to slow convalescence. Of even more value than the preemployment physical examination, in the prevention and control of occupational diseases and accidents, is the periodic check up. For this reason all employees exposed to special occupational hazards of sickness or injury should have a periodic medical examination. Just as the newer public health and industrial health focus attention on personal hygiene as of equal value with environmental sanitation, so also a newer public safety and industrial safety must emphasize the make up of the individual worker as contrasted with his environment and mechanical equipment. Accident prevention is becoming recognized as being dependent more and more on medical and psychologic examinations and the proper follow up and placement of employees.

Each industrial organization must decide for itself as to the future development of new phases of preemployment and periodic medical examinations, including routine roentgenographing of the chest and such tests as pertain to the nervous and mental qualities of the prospective employee. Mental hygiene in industry is only on the threshold of development. As interest grows in this important subject, which underlies the whole realm of safety and physical health, more and more industries will be thinking in terms of mental and nervous system examinations in connection with their routine physical appraisals. Although the majority of industries do not include blood and other tests for venereal diseases in their routine preemployment or periodic physical examinations, more and more companies are beginning to recognize the hidden costs in money and disability from accidents and sickness to which these diseases give rise. The prevention and control of syphilis and gonorrhea constitute a health and safety measure which should be of vital concern to the whole community.

FIRST AID

First aid is the most important adjunct of accident prevention and control, its study and practice promote safety mindedness or safety consciousness. Physicians must assume the leadership in the teaching of first aid, which has been defined as a "special branch of practical medicine and surgery, by a knowledge of which trained persons are enabled to afford skilled assistance in cases of accident and sudden illness, and through which prolonged or permanent disability may be prevented and life often saved."

Without elaborating on its details, which are more or less self evident, the following may be listed as an outline of the fundamental elements of an adequate first aid service

A First aid treatment

- 1 Immediate reporting of injuries for diagnosis and treatment, together with complete records
- 2 Conveniently located first aid treatment facilities
- 3 First aid work carried on under trained and experienced personnel
- 4 Adequate follow up of each case.

B First aid instruction

- 1 Instruction on principles and practice of emergency first aid, including particularly artificial respiration and the control of bleeding
- 2 Printed publicity, group talks, moving and talking pictures and bulletins on subject of first aid
- 3 First aid training classes, teams and contests, when practicable and feasible.
- 4 First aid committees and special campaigns and rallies to stimulate group interest

The five general principles to be applied as they may be necessary in the practice or teaching of first aid work are

- 1 Obtaining a doctor's services
- 2 Stopping bleeding
- 3 Restoring breathing
- 4 Making the patient as comfortable as practicable
- 5 Doing no more than is actually needed

ACCIDENT PRONENESS

From various recent studies it is now well established that certain persons have a special liability to be the subjects of accidents just as some individuals are particularly susceptible to diseases. Not only may a small percentage of a working group show a very high percentage of the total sickness disability in the entire group, but it has been found that as little as 10 per cent of a group may be responsible for as much as 75 per cent of the accidents occurring among them. Recent medical research has shown that "accident proneness" may be an innate characteristic of some individuals and a personal phenomenon independent of any question of responsibility, conscious action or blameworthiness. It has been found that those who sustain an undue number of one kind of accident also sustain an undue number of other kinds and that accident proneness is a relatively stable quality obeying definite laws so that if those persons who have an excessive number of accidents in their first year of employment and exposure were eliminated the subsequent accident ratio of the group would be considerably diminished. Some have gone so far as to suggest the possible desirability of actually eliminating those who show an undue number of accidents in an initial period of employment in order to reduce the subsequent accident rate of the group and as an important method of accident prevention. While it appears reasonable that a person should be removed from a position in which he is a potential danger to himself and others, industries realizing their obligations to society in general undoubtedly will be slow to penal-

ize an individual because, through no fault of his own his mental and physical qualities are not equivalent to those of his fellow employees. In this connection the chief objective should be to see that these accident-prone individuals, who may make up as much as one fourth of a working group, are identified through medical and other examinations and are assigned to work in which the severity and danger of their potential accidents are reduced to a minimum. Moreover, the accident prone generally are the least healthy, indicating that the prevention of accidents may depend to a considerable degree on the prevention of sickness and emphasizing further the need for greater attention to the entire health program. Individual accident susceptibility may be based on such factors as (1) the effectiveness of the visual apparatus, (2) reaction times (3) reduced energy, (4) the intensive and extensive distribution of attention, and (5) certain kinesthetic impressions or sensations and nervous reflexes making possible more or less automatic performance. Newer developments in regard to the relation of some of these factors to the incidence of accidents should be mentioned briefly in passing.

VISION

Aside from various pathologic conditions there are two factors which in the past have served to determine whether or not the eyes of an individual are functioning properly, these are refraction and muscle balance. Recent studies by Ames¹ and his co-workers indicate that there is a third newly discovered factor of importance, that is, the relative size and shape of the ocular images of the two eyes, a difference in which constitutes a condition known as aniseikonia. In such a condition, depth perception or stereoscopic vision is seriously disturbed and it is conceivable that such impaired vision may be a very important element in the causation of accidents. To insure perfect single binocular vision it is imperative to detect, measure and correct aniseikonia, and this may come to be one of the newer requirements in the control of accidents from the standpoint of vision.

REDUCED ENERGY

Accident proneness, or individual accident susceptibility, at times has been explained on the basis of physical, mental or nervous fatigue, such fatigue usually being interpreted as reduced or impaired energy due to some particular type of work, labor or exertion. Recent studies by Haggard and Greenberg² seem to indicate that drops in efficiency and productivity may not necessarily be related to actual fatigue and weariness relieved by rest, but that many cases of so-called fatigue are nothing more than reduced energy due to the need for and relieved by food.

A recent study of personal injury accidents made by one of our companies shows that the great majority of accidents of this nature occur between 10 and 12 o'clock in the forenoon and 3 and 5 o'clock in the afternoon. As the work involved and the rest periods available preclude the possibility of so-called industrial fatigue, it is conceivable that these accidents were related to reduced energy, which may have taken place with the approach of meal time and the need for food. While preliminary experimental studies point to the possible value of extra feedings in the midforenoon and mid-afternoon, to prevent loss in efficiency, effort or production and possibly to reduce accident susceptibility.

¹ Ames, Adelbert Jr. Aniseikonia. A Factor in the Functioning of Vision. *Am. J. Ophthalm.* 18: 1014 (Nov.) 1935.
² Haggard, H. W. and Greenberg, L. A. Diet and Physical Efficiency. New Haven: Yale University Press, 1935.

it would seem wise before attempting the expense and trouble of providing extra feedings as a routine to be sure that the industrial worker, the school child and the housewife have the necessary knowledge as to their average food needs for a day and that they become thoroughly acquainted with the fact that breakfast should be something more than a cup of coffee and that a sandwich is not a complete lunch, all of which, in the interest of safety as well as of health, argues for more instruction on diet and nutrition not only for household members but for school children and industrial workers. What first may be necessary is not more but better balanced meals, and this is largely a matter of education. Before advocating an increase in the number of meals per day, as some have done, it would be wise to make certain that the three regular meals are what they should be in quality and quantity.

NERVOUS REFLEXES

"The car went out of control" has been the explanation of many automobile accidents in the past. According to the recent suggestion of Henderson³ it often in reality is the motorist "who goes out of control," thus emphasizing further the fact that the newer public safety must concentrate more and more on the human element, including individual nervous reflexes and reactions. The so-called self-righting reflex caused by a sudden upset of equilibrium in an emergency and the more or less unconscious "extensor thrust" of the legs and feet are instinctive reactions which may result in a sudden pressure on the accelerator pedal of an automobile, thus causing a serious accident although the car itself and its motor, brakes and steering gear are in perfectly good order. All of which is a further indication that machines and equipment should be fashioned for the human individual and his safety, based on a complete knowledge of his physical requirements and nervous reflexes, which can be determined only by suitable medical examinations. Compulsory periodic testing of automobiles already is in effect in some states, required periodic medical examinations of all licensed vehicle operators should be the next step in highway safety.

HOME AND SCHOOL SAFETY

It is becoming more and more apparent that safety in the home should be the central objective and influence from which radiates safety in all other walks of life. To this end, instruction in safety practice is of paramount importance in the home. In this great work, no individuals are in a more strategic position to accomplish results through practical teaching than are the physician and the nurse.

Safety in industry, in the school, in public places and in travel has been built largely on the combined foundations of enforced regulations and education. In the home, on the other hand, most of our results in reducing accidents must be accomplished through education alone. Home accidents, as a rule, are due to ignorance, indifference or inadequate equipment. Both the human element and the home environment are the factors to be considered. To a large degree, the problem is one of education of individuals, preferably in family and home groups. Ignorance and indifference must be dispelled and proper methods of using home facilities and equipment must be taught.

Health and welfare problems more and more are being solved with the family and home as the unit to

be considered. So also the problems of safety must be approached through the home, not only for the benefit of the home itself, but also in the interest of furthering all phases of human safety. The family doctor in carrying on his functions as a teacher of health and a healer of disease should grasp every opportunity to teach the facts with reference to accident causation and prevention to the children and adults with whom he comes in contact. Moreover, medical examinations of individuals in family and school groups should be of as much value as examinations of industrial workers in bringing to light the accident prone and in serving as a background for safety education. Such medical examinations in industry, in the school and in the home will contribute also to the control and prevention of accidents in public places and in travel.

TRAINING OF PHYSICIANS

Finally, it may be stated that better facilities should be developed in our medical schools for teaching the medical aspects of accident prevention and of safety, and adequate graduate instruction should be made more generally available for those planning to specialize in these fields. Prospective doctors, many of whom eventually will be called on to render service particularly in the field of industrial accidents and safety, should be taught the principles of court procedure and testimony, the many aspects of liability and compensation, and the fundamentals of personnel administration and industrial relations. The medical curriculum is in need of various modern amendments to permit it to keep pace with the growing demands made on the intelligence and ability of the present-day physician. In no field are these demands greater than in that of preventive and industrial medicine, public health and safety.

195 Broadway

ABSTRACT OF DISCUSSION

DR. JOHN H. OGILVIE, Kansas City, Mo. I was interested to see that Dr. Bristol's problems in the prevention of accidents have been very similar to mine in a work that is entirely dissimilar to his, that is, the same factors are present in Dr. Bristol's work and in mine. I should like to show some results of this individual whom he calls the accident-prone individual. He is a very potent source of expense in industry. Years ago I began a study to see what I could do to reduce my medical costs. Some interesting things were found. First, the medical cost and the proportion of serious accidents were in direct proportion to the number of minor accidents; second, that 16 per cent of individuals were contributing about 66 per cent of the accidents, so I began a study of this small group of individuals. After suggestions from medical men and safety engineers, and all the safety devices we could devise, I found that the proportion of accidents was still too high. I began a further study to determine the cause of these accidents and came to the conclusion to which Dr. Bristol has come, that there is an individual who is accident prone. I find that this individual falls into three classes: (1) the individual who is hindered by some major or minor physical defect, (2) the individual who is in a job that is not suitable to him and (3) the individual who is accident prone simply because he cannot be educated. He is the person who is involved in a great many of the major accidents. He is analogous to the man who walks across the street through a stream of traffic reading his newspaper. In the first group I found that by repeated examinations during the course of employment that individual could be eliminated, that is, by sending him to his local doctor and making suggestions to him, I could correct him. In the second group by being fitted into a job which was suitable for him, the individual could be corrected. In the third group, individuals who could not be educated in spite of an educational campaign and safety hazards education, the only thing that had any effect was disciplinary measures. Only 30 per cent of the accidents to

³ Henderson, Landell. How Cars Go Out of Control. Analysis of the Driver's Reflexes. Science 82: 603 (Dec. 27) 1935.

which I have been referring that occurred ten years ago are now happening. I am glad that Dr. Bristol has drawn attention to these things that are associated with this accident-prone individual.

DR. LOUIS J. HIRSCHMAN, Detroit: I offer an apology for speaking at this meeting because I practice clinical medicine, however, I am a member of the Michigan State Council of Health and I am interested in public health as well as in the individual. I also come from a city where the most dangerous weapon on which man has his hands—the automobile—is manufactured. It is said that automobile accidents are responsible for more lives lost than any other one class of hazards. Much is heard about the drastic action of courts on careless drivers, but it seems to me that a leaf should be taken from the book of the Department of Commerce in connection with the rigid examinations of airplanes as well as of pilots. There should be in a lesser degree, some definite method of periodic examination of automobiles with regard to brake control as well as an examination of the weakest part of the automobile, that is 'the nut at the wheel.' There should be some way of examining him before he receives his driver's license—an examination by his family physician the same as in the case of the locomotive engineer, the bus driver and the taxi driver. If definite action could be taken by which municipalities would insist on more than a cursory examination of drivers and the physically and mentally unfit eliminated, a great deal would be done toward improving the medical aspect of accident control.

DR. STANLEY H. OSBORN, Hartford, Conn.: I think that the last speaker has landed in the middle of an interesting problem. I should like to make a motion that the incoming chairman of the section appoint a committee on accident control and safety to study the medical aspects of accident control and make recommendations to the next annual meeting.

EXPERIMENTAL PRODUCTION OF MALIGNANT GROWTHS IN MICE BY ESTROGENIC CHEMICALS

WILLIAM U. GARDNER, PH.D.
GEORGE M. SMITH, M.D.
LEONELL C. STRONG, PH.D.
AND
EDGAR ALLEN, PH.D.
NEW HAVEN, CONN.

The role of chemical stimulation in the development of mammary tumors postulated clearly by Loeb¹ in 1919 has been demonstrated experimentally by several investigators.² The present report summarizes additional experiments on the effect of several different chemical stimulants (estrogenic hormones³) on the development of mammary carcinomas and of subcutaneous sarcomas in three different strains of mice.

As new features may be listed: (1) the development of sarcomas at the sites of injections in nongenital tissues following treatment with estrogenic hormones⁴ which have formerly been considered specific stimulants to the genital tissues, (2) the production of mammary cancers in mice by four different estrogenic

chemicals (theelin, keto-estrin benzoate, hydroxyestrin benzoate and equilin benzoate), (3) the production of mammary carcinomas in an inbred strain of mice which had previously been considered relatively cancer resistant.

One or two estrogenic chemicals have been injected for periods exceeding 125 days into 126 mice of three strains as follows: eighty-six mice of the A strain, twenty-seven mice of the C₃H strain, and thirteen mice

Summary of Experiments with Concentrated Estrogens in Mice

| Strain | Sex | No of Mice Treated | No of Mammary Tumors | No of Sarcomas | No Still Living With Tumors | Percentage Dying with Tumors |
|------------------|-----|--------------------|----------------------|----------------|-----------------------------|------------------------------|
| A | ♀ | 20 | 7 | 0 | 1 | 37 |
| | ♂ | 66 | 0 | 1 | 16 | 18 |
| C ₃ H | ♀ | 9 | 2 | 0 | 4 | 40 |
| | ♂ | 18 | 8 | 6 | 0 | 77 |
| CBA | ♀ | 8 | 2 | 0 | 5 | 100 |
| | ♂ | 5 | 0 | 0 | 3 | 0 |
| Totals | | 120 | 28 | 7 | 29 | |

of the CBA strain, both males and females as shown in the table. Untreated breeding female mice of the A and C₃H strains normally develop a high percentage of mammary tumors, while those of the CBA strain very seldom develop such tumors.

Up to the present time a total of twenty-eight mice receiving estrogenic hormones have developed mammary tumors and seven have developed spindle-cell sarcomas in intimate relation with retained oil cysts at the sites of injection.

STRAIN A

Sixteen mammary tumors have been observed in the eighty-six mice of strain A which have been treated for 125 days or more, seven of these occurring in non-breeding females and nine in males. The tumor incidence in virgin females of this strain has not been determined but the injected female mice, when injections of large amounts of estrogenic hormone are started in the first week or two of life, might be considered as equivalent to ovariectomized females because the ovaries remain very small and mature follicles or corpora lutea do not form. Tumors have developed in both male and female mice of this strain receiving keto-estrin benzoate, hydroxyestrin benzoate and equilin benzoate. Mice receiving theelin, theelin or equilin have not developed mammary tumors up to this time. All but one of the mice developing mammary tumors received 500 international units of estrogenic chemical or 0.1 mg of equilin benzoate weekly, the injections starting at from 1 to 119 days of age and continuing for periods up to one year. The estrogenic activity of the amounts of theelin, theelinol and equilin injected have been smaller than those of the other estrogenic chemicals.

A spindle-cell sarcoma developed in association with a retained oil cyst at the site of injections in a male mouse receiving keto-estrin benzoate (British Drug House).

STRAIN C₃H

Nine female and eighteen male mice of the C₃H strain have received either keto-estrin benzoate, hydroxyestrin benzoate, theelin or theelin in combination with keto-estrin benzoate. One male receiving theelin and seven males receiving weekly injections of 500 international units of keto-estrin benzoate developed mammary tumors. No tumors developed in three females receiving similar treatment. Two of six

virgin females receiving 100 international units of hydroxyestrin benzoate weekly developed mammary tumors

Spindle-cell sarcomas developed in the five male mice which received theelin in aqueous solution followed by keto-estrin benzoate in oil, and a sarcoma developed in one of the eleven mice receiving only keto-estrin benzoate in oil

STRAIN CBA

Keto-estrin benzoate and hydroxyestrin benzoate have been given at the rate of 500 international units weekly to eight female and five male mice of strain CBA. Two of the female mice have developed mammary cancers. Eight of the thirteen mice are still living without tumors, though four of these have been treated for over one year

SUMMARY

A total of 126 mice of three inbred strains have received estrogenic hormones for periods of 125 days or more. Twenty-eight mice have developed one or more mammary carcinomas and seven more have developed spindle-cell sarcomas as local reactions in relation to retained oil cysts at the sites of injection. Mammary cancers have developed in male mice receiving theelin, equilin benzoate, keto-estrin and hydroxy-estrin benzoate. Mammary tumors have occurred in two of three females of the relatively tumor-resistant CBA strain

Clinical Notes, Suggestions and New Instruments

FURTHER REPORT ON CASE OF REMOVAL OF RIGHT CEREBRAL HEMISPHERE

JOHN D O'BRIEN M.D. CANTON OHIO
Attending Neuropsychiatrist Mercy Hospital

In September 1932 I¹ presented the report of a case in which the right cerebral hemisphere was removed. Subsequently Dr W James Gardner² of Cleveland, who performed the operation, presented a further report. A married woman, aged 31, mother of two children, had generalized convulsions for ten years, occurring from two to four times a year. Later they assumed a jacksonian type and involved the left side of the body. The attacks were preceded by a sensory aura of intense burning in the palm of the left hand. For two months prior to observation, blurring of vision, beginning left paresis, headache, vomiting and a marked disturbance in the emotional sphere were noticed. The examination revealed clonic convulsions affecting the left side of the face and neck and occasionally the left arm. Bilateral papilledema was present, with a complete left homonymous hemianopia. Left hemiparesis affected the face, arm and leg. For the sensory component, tactile perception was greatly impaired over the entire left side of the body. Pain, thermal position and vibratory perception appeared to be entirely lost. The spinal fluid pressure was 300 mm. of water. The clinical diagnosis was tumor of the right temporoparietal region.

Aug 31, 1931, Dr Gardner performed excision of the right hemisphere. The patient's convalescence was indeed gratifying. She was able to return to her home and family later to assume the duties of her household, gaining strength and considerable weight, and remaining entirely free from convulsions. The deformity existing prior to the operation, left hemiparesis, slight facial asymmetry and sensory disturbance, remained with her to the end. In the mental sphere she appeared stabilized, and there was no evidence of emotional instability. She did appear to the casual observer to be slightly apathetic at times,

but to her intimate friends I am unable to learn of any evidence of mental deterioration or marked personality change.

Two questions frequently asked were whether there was any change in her appreciation of distances and whether she had the same sense of the passage of time. I was unable to detect any abnormality at any time in this direction. Her memory for recent and past events was good, and she read constantly in spite of her eye difficulty. The sense of smell on the right side was lost, because the right olfactory bulb was destroyed. The sense of hearing in the right ear with the audiometer was undisturbed.

She took the usual interest in her children and attended very well to her household duties. She inquired and was anxious to know all the details of her operation, which was explained to her, and she was extremely grateful for what had been done for her.

Nov 20, 1935, while about her home, she tripped and fell a distance of about 20 feet. She was able to get up and go about for a few days, when she collapsed. Following this she became very apathetic, presenting marked delay in all mental reactions, it was necessary to feed her, and memory for both past and recent events was very much disturbed. Involuntaries appeared and the spatial sense was quite disturbed, in addition to a marked disturbance of vision.

Lumbar puncture revealed bloody fluid, and it was felt that she had a subdural hematoma on the left side. Dr Purdy trephined over the left parietal eminence, under local anesthesia, and considerable clotted blood was removed. A lumbar puncture needle was inserted in the old trephine opening in the right cranial cavity, and the removal of about 50 cc of bloody spinal fluid caused the brain to collapse and later appear in the field of operation. Simultaneously she complained of headache and at this moment appeared talkative and very responsive to all stimuli. She appeared to be in good condition for several days, when she lapsed into her former apathetic state. Repeated puncture through the original trephine opening in the right cranial cavity and the withdrawal of about 20 cc. of blood-tinged spinal fluid caused her to appear brighter and more interested for brief intervals, until this finally failed to affect a change in her condition.

Bedridden, decidedly apathetic, with involuntaries, aroused only with great difficulty, giving the appearance of one decerebrated, she died March 4, 1936.

Strenuous efforts to obtain an autopsy were met with absolute refusal on the part of the family. This I regret very much to report, as we were interested to learn the exact pathologic condition present. Several questions remain unanswered. Did the fall and subsequent hemorrhage cause her death? or did the fall bring about a recurrence of the growth and its subsequent extension and rapid growth play a part in her death? An autopsy would have answered both questions.

Excision of the right hemisphere is not a very common procedure, it is an operation of great magnitude. From what I can gather in medical history this patient survived longer than any who have undergone a similar operation, in addition it provided this woman with almost five years of happiness with her family. Her death, having all the characteristics of an accident, leads one to wonder how long she might have lived if the accident had not occurred.

A most striking feature in this case, the operation of unusual magnitude attended with a minimum amount of disability, would lead to the consideration of the importance of the basal ganglions and the care exercised to avoid injuring them—a triumph for surgery.

Medical Arts Building

Temperature in the Stratosphere—The temperature of the atmosphere dropped gradually during ascent from 0 F at 16,700 feet to -71 F at 37,600 feet, where the balloon entered the stratosphere. As the balloon continued to ascend, the temperature curve fluctuated sharply over a small range and the lowest temperature, -81 F, was recorded when the balloon was at 68,000 feet and descending. At 37,600 feet during descent, as the balloon left the stratosphere, the temperature began to rise steadily and rose from -70 F to about +30 F at 2000 feet altitude.—Armstrong, H G. The Medical Aspects of the National Geographic Society-U S Army Air Corps Stratosphere Expedition of Nov 11, 1935, *J Aviation Med* 7 55 (June) 1936.

Council on Pharmacy and Chemistry

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORTS

PUBLISHED BY PAUL NICHOLAS LEECH, Secretary

TRICHOPHYTIN AND OIDIOMYCIN

Preliminary Report of the Council on Pharmacy and Chemistry

In 1932 the Council issued a preliminary report on Trichophyton Extract (Trichophytin-Metz) stated to be a mixture of various species of trichophyton, postponing consideration of that product to await development of further clinical evidence for the value of trichophyton therapy from the work of American dermatologists (THE JOURNAL, Nov. 10, 1932 p. 1779).

Last year the Lederle Laboratories, Inc., requested Council consideration of its Trichophytin and Oidiomycin.

Trichophytin is defined as "The soluble broth culture products of Trichophyton interdigitale" and is prepared for use as a desensitizing agent in chronic ringworm infection due to Trichophyton interdigitale.

Oidiomycin is defined as "The soluble broth culture products of Monilia albicans" and is prepared for use as a desensitizing agent in chronic ringworm due to Monilia albicans.

The firm submitted trade packages of the preparations both for diagnosis and for treatment. The Council found the trade packages unobjectionable, but some criticisms of an advertising circular were transmitted to the firm. These were submitted by the firm to Dr. M. B. Sulzberger and on the basis of his reply the differences of the firm and the Council in this matter were ironed out.

In support of the claim for recognition of Trichophytin and Oidiomycin, Lederle Laboratories, Inc. furnished references and several reports. Of course, much work on intradermal tests and intradermal therapy, using extracts of various fungi, has been carried on for some years, notably by Jadassohn, Bloch and their pupils in the Breslau and Zurich dermatologic clinics. In this country Sulzberger and Wise, Williams, Peck, Hopkins and others have also made many contributions. This entire subject is well summarized by Kerr, Pascher and Sulzberger (*J. Allergy* 5:288 [March] 1934), who state that work has been done to show that patients hypersensitive to trichophyton extracts may be desensitized by repeated intradermal tests—a certain number of whom are remarkably benefited. A certain number that seem to be refractory to trichophyton desensitization will be found to be suffering from a monilia infection. These fungi are found on all skins, on the hair and nails and in the mouth and gastro-intestinal tract, they may cause eczematous eruptions and will show positive patch tests (Ravaut, Sulzberger, Wise, White, Becker, Shelmire). The authors, therefore, recommend the use not only of trichophyton extracts (Trichophytin) in dermatomycoses but in many instances also the use of monilia extracts.

These investigators employed for preparations of oidiomycin a pathogenic strain of Monilia albicans from a severe moniliasis of the skin and for the trichophytin a strain of Epidermophyton interdigitale from a severe eczematous mycosis of the feet. They found it normal for a patient to have a slight to moderate reaction to 0.1 cc. of oidiomycin in a dilution of from 1:500 to 1:100. The Council believes this makes it difficult to justify the use of such a test by the practitioner not versed in the work. The authors believe a trichophytin hypersensitivity and an oidiomycin hypersensitivity are to be separate and distinct. In both cases it must be recognized that while a positive test is specific and indicates that the patient at some time or other in the past has had an infection yet the test is not necessarily diagnostic of the present condition. The authors used this material for treatment of puzzling eczematous ringworm principally of the hands and feet. Diagnoses were made clinically and by intradermal tests. In the twelve cases reported in some instances the eruptions "flared up" as a result of the

injections, indicating the specificity. Asthmatic symptoms even were noted following injection in one case. It was shown that desensitization was possible in some of the cases and the authors recommend combined trichophytin and oidiomycin desensitization in persistent cases of eczematous hand and foot eruptions due to fungi.

The Council's referee reported on an unpublished manuscript submitted by the firm, "Trichophytin and Monilia Extracts in Allergic Eczemas," by Edna S. Pennington, M.D., Department of Medicine, Vanderbilt University Medical School. The patients reported on in this article were questioned and tested for personal and family allergy and examined for evidence of ringworm infection (whether there was cultural and microscopic investigation is not stated), and the skin was tested with the two extracts. With the oidiomycin in a dilution of 1:100 were used Trichophytin-Lederle 1:30 and Trichophytin-Metz 1:50, in doses of 0.1 and 0.5 cc. Reactions locally were either immediate wheal reaction or delayed, reaching their height in from twenty-four to forty-eight hours. Trichophytin-Lederle and Trichophytin-Metz gave parallel results. Thirty-three cases are reported. In the first group of twelve no treatment except injection of trichophytin and oidiomycin was used and of these subjects nine are reported as completely cured, one definitely improved and two unimproved. In some of these cases skin lesions had been present for twelve years or longer. The second group, in which other measures were used, are, of course, for the purpose of this consideration, valueless.

Robinson and Grauer (*Arch. Dermat. & Syph.* 32:787 [Nov.] 1935) also report on the use of autogenous and stock fungus extracts in the treatment of mycotic infections. They make the following statement (p. 789):

While it is not the rule it is possible for persons not infected either with Trichophyton or with Monilia to give a positive cutaneous reaction to the extracts of these fungi. Hence a certain degree of error results when such persons are considered to be infected with fungi in the absence of proof obtained by culture. Conversely, it does not follow that in all cases fungous infection produces a state of demonstrable sensitization. It was fairly common in our series for a mycotic infection to be present without a positive cutaneous reaction to the autogenous extract.

Dr. Sulzberger, the consultant of Lederle Laboratories, Inc., states that this quotation should read:

While it is not the rule it is possible for persons at the time presenting a manifest infection either with Trichophyton or with Monilia to give a positive cutaneous reaction to the extracts of these fungi. The finding of fungi in culture in a focus is no proof that the distant dermatosis is actually attributable to the fungi found in the focus. Hence, a certain degree of error results when such persons are considered to be infected with fungi in the absence of proof obtained by culture.

The Council makes no objection to the revised version of the statement, it points out that the first quoted statement is taken verbatim from the Robinson and Grauer article.

Robinson and Grauer report a series of cases treated with autogenous extracts, many of them of long duration, and a fair proportion they considered cured. Also a further group, in which no culture was grown, was treated with stock material and sixteen out of twenty-three are reported as cured. They give warning as to the necessity of regulating the intradermal dose for the sensitization of the particular patient.

Tolmach and Traub (*Arch. Dermat. & Syph.* 28:560 [Oct.] 1933) discuss epidermophytid and the trichophytin reaction. Sensitization is accepted as the factor in the production of secondary fungus eruptions.

Most of the concomitant eruptions on the hands in patients suffering from dermatomycosis of the feet are supposed to be epidermophytids. As the authors state, the diagnosis of epidermophytids is based on the following criteria: "(1) the findings of fungi in the lesions on the feet (2) the absence of fungi in the lesions on the hands and (3) a positive reaction to the intradermal injection of trichophytin." In a carefully studied group of thirty-eight cases microscopic and cultural studies being made, they found: (1) no relation between the severity of the infection and the response to injections of trichophytin (2) only twenty-three out of the thirty-eight cases showing a positive reaction to trichophytin (3) Monilia occurring in five cases four of which reacted to trichophytin (4) eight cases having demonstrable fungi in lesions of the feet gave negative

responses to trichophytin, (5) patients giving negative reaction to repeated injections of trichophytin if different sites were used, a positive reaction occurring frequently when the site of a previous injection was used. The authors doubt the specificity of trichophytin. In discussion of the paper, Williams of New York stated that the whole question is still obscure.

Study of the literature as illustrated by the excerpts given, and consideration of the data furnished by Lederle Laboratories, Inc, force the Council to conclude that while there seems to be a certain amount of specificity in the intradermal tests and therapy with trichophytin and oidiomycin in dermatomycoses, nevertheless it has not yet reached the place where it can be unreservedly recommended to the general medical profession.

The Council therefore voted to postpone consideration of Trichophytin and Oidiomycin of the Lederle Laboratories, Inc, to await confirmatory evidence of their value.

IGOL ORAL AND IGOL G U NOT ACCEPTABLE FOR N N R

Igol is the proprietary brand name under which Surgident, Ltd, West Hollywood, Calif, markets a series of iodine preparations. The firm presented Igol Oral and Igol G U for the Council's consideration. Two additional preparations mentioned in the advertisements but not in the presentation are Dental Igol 10% and Igol Surgical Dressing (a vaseline ointment).

According to the information submitted by the manufacturer, the Igol preparations are mixtures of iodine, gallotannic acid, glycerol, phenol and other ingredients to be mentioned later. The chemical synonym is said to be "Glycerodigallophenodin." That this is a name without significance is admitted by the firm in the following sentence in the firm's presentation: "by this name it is not meant to infer that the active ingredient is a chemical individual of known composition. This name was given to indicate the various constituents." The firm states, however, that "on the advice of our consulting chemists in making up future labels and literature this synonym is to be dropped as connoting unestablished definiteness of chemical structure."

The Igols are recommended as antiseptics for the treatment of a variety of bacterial infections of the skin, mucous membranes and wounds. Different preparations have been devised for application to different parts of the body.

It is claimed that the treatment of glycerol with iodine vapor produces an "impregnation of the glycerin molecule with nascent iodine to any desired concentration up to 30%." The activity of Igol is attributed to "free iodine in equilibrium with an unstable iodine compound whose composition has not yet been determined."

The firm has submitted samples of Igol Oral and Igol G U (Genito-Urinary) and the following documents:

- I A volume containing typewritten reports on
 - 1 The Characteristics of a New Group of Antiseptic Preparations Known Commercially as Igols by Leo T. Samuels, Ph.D.
 - 2 Pathologic reports on tissues treated with Igols and other disinfectants (illustrated) by Dr. Howard A. Ball.
 - 3 Preliminary Clinical Report on Igol G U, by Dr. Waldo Pendleton.
- II A folder entitled Igol Surgical Dressing
- III A folder entitled Igol 10%
- IV A circular in the form of a single sheet entitled Dental Igol 10% and Igol Surgical Dressing.

The composition of the Igols is variable. Some of this variation is intentional, some appears to be due to uncontrolled iodination of the glycerin. Igol Oral is said to contain approximately 10 per cent iodine, Igol G U approximately 6 per cent iodine. Igol 10% "iodine elemental 2%, organic iodates 8%", Igol Surgical Dressing "elemental iodine not less than 1.5%, combined iodine 2.5%."

Dr. Samuels' analysis is said to show that the preparation contains "iodine in the form of a compound which readily releases more iodine as that in the free state is removed." This was determined by successive shaking of Igol with carbon tetra-

chloride. The special method used by Dr. Samuels for these determinations is not accepted by the A. M. A. Chemical Laboratory without further evidence. If the preparation were to be recommended for acceptance, this problem would be studied by the A. M. A. Chemical Laboratory. The Council's referee reported that he was not convinced by the descriptions that Igol contains an iodine compound in unstable equilibrium which gives off free iodine (at least in appreciable amounts) as the previously present free iodine is removed.

The bacteriologic tests with cultures of *B. typhosus* and *Staphylococcus aureus* indicate that the phenol coefficients of several Igol preparations are 0.78 and 0.79, while that of U. S. P. tincture of iodine was found to be 11.1.

Igol Oral sterilized infected rabbit skin in five minutes or longer in a number of trials but was considerably inferior to tincture of iodine. An "Igol alcohol-aqueous" preparation used in these tests, though it was not mentioned in the presentation, appeared to be almost as effective as a skin disinfectant as tincture of iodine. Considering that both are alcoholic solutions of iodine, this result is not astonishing.

Claims are made that the Igols are less irritant and less destructive of tissue than U. S. P. tincture of iodine. The pathologic reports support this statement. Diluted tincture of iodine might be equally nonirritant. Persons sensitive to iodine would no doubt be affected by Igol. Dr. Pendleton records a case of "first degree burn" due to the application of Igol.

Claims that the Igols promote healing of wounds and are beneficial in the treatment of Vincent's angina, infected tooth sockets, pyorrhea, genito-urinary infections and infected wounds are not substantiated by any of the material submitted by the firm.

Igol was submitted to the Council on Dental Therapeutics. The excellent report of this body was courteously made available to the Council. The Council is indebted to it for the following information:

1 U. S. Patent 1,896,171 agrees essentially with the claims for Dental Pyodin, which was previously considered by the Council on Dental Therapeutics and denied acceptance for Accepted Dental Remedies.

2 The composition of Dental Pyodin is similar to that stated for Igol.

3 From these facts the referee for the dental council concluded that Igol was produced in the effort to continue the promotion of Dental Pyodin under another name.

4 Iodotannic Syrup, N. F., is somewhat analogous in composition to Igol.

5 The referee for the Council on Dental Therapeutics who made chemical tests of Igol obtained results which made him skeptical of the claims for Igol and its supposed ability to liberate free iodine available for action on bacteria under conditions existing in living infected tissues.

The firm informed the Council that Igols were being distributed only to physicians through the usual recognized channels and that there has been no advertising or sale to the public. The advertising has been done by mailing of the circulars referred to. The Council is not clear about the firm's meaning here, as the circulars are marked "Package or Professional Distribution." In addition to their content in unestablished claims, these circulars contain references to diseases by name. They are quite unacceptable, especially as package circulars.

The name Igol is uninformative, the firm states it is coined from I for iodine, G for gallotannic acid, OL for glycerol.

The Council declared Igol Oral and Igol G U unacceptable for inclusion in New and Nonofficial Remedies because they are preparations of uncertain composition and of needless complexity, marketed with unwarranted therapeutic claims under an uninformative proprietary name.

The foregoing report was submitted to the firm before publication. The firm replied, objecting to the reports of the Council on Pharmacy and Chemistry and of the Council on Dental Therapeutics. Additional material was submitted by the firm in support of its objections. A review of this does not sub-

stantiate the objections to the reports, in the opinion of the Council. The firm, having apparently failed to consider the nature of the objection to the name, requested its reconsideration. The Council did not feel that reconsideration was in order and authorized publication of this report.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

FRANKLIN C. BING, Secretary

LIBBY'S HAWAIIAN PINEAPPLE JUICE OMITTED FROM THE LIST OF ACCEPTED FOODS

The Hawaiian Pineapple Juice of Libby, McNeill & Libby, Chicago, was accepted by the Council Aug. 31, 1934, with the permissible claim that it contains from 9 to 11 Sherman units of vitamin C per ounce and that it is practically equivalent to fresh fruit juice in nutritional values (vitamin C slightly reduced). In December 1935 the following statement was received from the concern together with the request that acceptance be withdrawn:

The company contemplates no change in its methods of manufacturing Pineapple Juice and there is no intention on our part to deviate from the principles embodied in the rules and general decisions of the Council as we understand them.

In good faith, therefore, the Council drew up an announcement of withdrawal of acceptance based on the request of the manufacturer. Since that time, however, advertising for the product which has appeared in publications such as the *Saturday Evening Post* obliges the Council to recast its previous statement and to inform the medical profession of the status of the product in the light of the claims now advanced. In general, the product is being advertised both as a drink to yield energy and as a food to be used in the ever popular reducing diet propaganda. The following statements are illustrative:

We need a quick energy breakfast drink in Hawaii.
It supplies us morning energy.

Accompanied by an illustration of a slender young woman measuring her girth around the hips are these comments:

Go down weight!
Ever hear of a reducing diet which didn't call for pineapple juice?
Libby's natural juice is a satisfying liquid—always tempting, never fattening! It helps you cut down on heavy food. It's a source of vitamins A, B and C, iron and copper. All these help you keep going on a reduced diet.

It is noted that the "body-building" motif has been incorporated in the copy. Thus, Libby's Pineapple Juice is recommended:

To keep the sniffles away. There's nothing better than the fruit tonics in a pure natural juice to build up your resistance. If you already have a cold or feel one coming on, drink 2 or 3 large glasses daily. It furnishes extra energy, vitamins and other protective factors you need to combat colds.

Accompanying the picture of an elderly gentleman are the following suggestions:

"Good bye morning acidity! And its effect on your body is to build up your alkaline reserve. High in alkalizing factors, science commends it to help you avoid acidity in a way that's really pleasant."

This advertising appears to be an artfully designed piece of deception to enmesh those uninformed in nutrition. Libby's Pineapple Juice cannot be considered a "quick energy drink" any more than many other foods. The expression "quick energy" is misinformative and therefore misleading. The claim that Libby's Juice is "never fattening" conflicts of course with the claim that it yields "morning energy." The reader would be led to believe that Libby's Pineapple Juice should be included in reducing diets because of its vitamins A, B and C, iron and copper. This pineapple juice is no more effective for reducing

weight than are many common foods. The amount of iron in Libby's Pineapple Juice, 37 parts per million, is too small to warrant mention as an iron-containing food. As far as available evidence shows, the necessity of copper in human nutrition has not been established, claims that copper need be particularly considered in the selection of foods are therefore not acceptable.

The maintenance of resistance and health are dependent on adequate nutrition, exercise, rest, hygienic environment and sound habits plus other intangible prerequisites which are difficult to define. It is ludicrous to suppose that Libby's Pineapple Juice would keep one from getting colds. The usual well balanced diet includes many alkali yielding foods—milk in its various forms, fruits and vegetables. Acid-forming diets are not a practical nutritional problem because a good modern mixed diet adequate in minerals and vitamins can scarcely be potentially acid. Stress on "alkaline reserve" claims therefore is unwarranted.

This advertising is reminiscent of the blatant "patent medicine" and nostrum blurbs of the past. The advertising treats an ordinary food as a therapeutic agent, which it is not. Perversions of advertising of this character bring good advertising into disrepute and harm the majority of the food trade that conscientiously attempts to deal fairly.

The company, when informed of the objectionable nature of these claims, replied in part:

As for our Pineapple Juice advertising we believe that the statements made are warranted both as to fact and language and are necessary to express those facts to the lay public.

The company was requested to consider the foregoing report and to present any evidence which it might have in support of the claims made. In reply, the company furnished a statement by Dr. John A. Killian, Ph.D., formerly director of biochemistry, New York Post-Graduate Medical School and Hospital, and now a private chemist in New York, is the same Dr. Killian mentioned in the reports by the Bureau of Investigation of the American Medical Association on *Scot Tissue* (THE JOURNAL, July 16, 1932, p. 241) and *Croxon Cream* (Aug. 20, 1932, p. 672).

The type of argument presented by Dr. Killian is illustrated by the following quotations:

A ketosis is indicated whenever the respiratory quotient falls to a level of 0.76. Ketosis is characterized by subnormal physical efficiency, subnormal mental efficiency and an inability to get going and it may progress to the degree of resulting in stupor or even coma. Frequency of respiratory quotients below 0.80 in the morning after a night's fast indicates a state of actual ketosis or on the borderline of ketosis. Through its effect upon the alkaline reserve of the blood plasma and the antiketogenic effect of these carbohydrates the pineapple juice relieves promptly morning ketosis. A glass of pineapple juice consumed the first thing in the morning will promptly relieve i. e. within 30 minutes the ketosis described above.

In the opinion of the Council, the exploitation of the antiketogenic effect of pineapple juice is unjustified. There are many foods containing dextrose or other sugars which are just as capable as pineapple juice of elevating the respiratory quotient.

In the opinion of the Council these and the other comments offered by Dr. Killian do not warrant any alteration of the report. Claims that the consumption of pineapple juice builds up the resistance of the body against infections of the upper respiratory tract and that Libby's Pineapple Juice is of particular significance in the reduction of weight are no more warranted than the fantastic claim that the consumption of pineapple juice will "sweep aside morning acidity."

A further communication from the company states in part: "We have given careful consideration however to the Committee's ideas and it may be our future advertisements will more nearly meet the Committee's line of thinking." Such action would be highly commendable. In view of the present evidence however the Council voted that Libby's Pineapple Juice be removed from the list of accepted foods because the product is promoted in conflict with the Council's rules by the use of grossly exaggerated and unjustifiable claims which are believed to be seriously misleading to the public.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

DATA FOR THE ACADEMIC YEAR 1935-1936 PRESENTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The report presented herewith for the academic year 1935-1936 contains statistical data and editorial comment regarding existing medical schools approved by the Council on Medical Education and Hospitals¹. Included are revised lists of hospitals approved for internships and residencies in specialties. Also reproduced in the following pages are the Essentials of an Acceptable Medical School, the Essentials of an Acceptable School of Occupational Therapy (adopted by the House of Delegates in 1935), the Essentials of an Acceptable School for Physical Therapy Technicians and the Essentials of an Acceptable School for Clinical Laboratory Technicians (adopted by the House of Delegates in 1936). The Council's first inspection of schools for physical therapy and laboratory technicians based on the last two named essentials has been completed and lists of schools already found acceptable appear in the following pages. The publication of a list of acceptable schools of occupational therapy has been postponed until after Jan. 1, 1939, to allow time for certain schools to make the necessary changes.

Seventy-seven medical schools in the United States and ten in Canada, 705 hospitals approved for internships and 410 hospitals offering approved residencies in specialties are referred to in the tabulations presented.

These data are based on official reports from the institutions listed. Acknowledgment is tendered the officers of the bodies mentioned and others for their ready cooperation in supplying the facts included in this presentation as well as for other material furnished throughout the year enabling the Council to maintain its medical student and hospital registers efficiently.

SURVEY OF MEDICAL EDUCATION

Visitation of the schools has been completed and the compilation of data is in progress. Attention may again be directed to the overcrowding and understaffing of many of the schools. Speaking generally, the problem of securing clinical facilities adequate in kind and amount, under university control, so far as the appointment of clinical teachers is concerned, has not been satisfactorily solved. Correlation of the training and experience of teachers with the degree of responsibility assumed has still to be achieved. The selection of students, on a qualitative rather than a purely quantitative basis, is a problem calling for the best efforts of admission authorities.

From our observations it is evident that medical libraries need to be still further developed. Research needs greater encouragement. Salary scales, in the lower brackets, must be revised. Didactic methods of teaching in the clinical subjects prevail to an unwarranted extent. Substantial improvement along these and other lines will involve considerably greater financial support. The public should be brought to a realization of the fact that the well trained physician is a

costly product and that, unless medical education receives adequate public support, inferior medical service will be the inevitable result.

PREMEDICAL EDUCATION

The minimum of collegiate credit required for entrance to medical schools in order to meet the Council's standards since 1918 has been two full academic years, including English and theoretical and practical courses in physics and biology and in general and organic chemistry, completed in institutions approved by accrediting associations acceptable to the Council. These agencies are:

- Association of American Universities
- Middle States Association of Colleges and Secondary Schools
- New England Association of Colleges and Secondary Schools
- North Central Association of Colleges and Secondary Schools
- Northwest Association of Secondary and Higher Schools
- Southern Association of Colleges and Secondary Schools

Since 1915 the Council has published a list of approved colleges of arts and sciences and junior colleges as a guide to medical schools in the selection of students and also to assist the prospective medical student in choosing a college for his premedical training.

Medical schools are privileged to accept applicants who have fulfilled the requirement in American and Canadian institutions not approved by the agencies mentioned, provided the applicant gives evidence of superior ability.

The preliminary prerequisite of the Council is outlined in detail in the Essentials of an Acceptable Medical School, which appears on page 684.

The Council's requirements and those of the Association of American Medical Colleges, in which practically all approved medical schools hold membership, do not materially differ.

The College Association also endorses the list of evaluating agencies mentioned before but in addition recognizes the colleges approved by a state university.

College grades, the medical aptitude test and personal interviews serve as a basis for selection. The House of Delegates of the American Medical Association at the Kansas City session recently transmitted to the Council the recommendation included in a resolution, which was adopted, that entrance requirements to the medical courses of the educational institutions of the United States be conditioned on the character, personality, adaptability, social fitness and motivations of the applicant as well as on his academic training.

The organizations interested in the improvement of medical education do not attempt to outline courses that should be taken in the secondary school.

For the session 1936-1937, forty-five medical schools in the United States have adopted requirements in excess of the minimum, i. e., four require a degree, thirty-six require three years, one requires four years, three schools will admit students with three years of

¹ Including three schools which are not fully approved. See footnotes to table 1, page 663.

(Continued from page 661)

college work if the baccalaureate degree is conferred in absentia at the end of the first year in medicine, and one school has a requirement equivalent to two and one-half years. The medical schools in Canada also vary in their preliminary requirement. One requires a degree, one has a three year prerequisite, three require two years, one requires one year, and four schools have a six year medical course including premedical studies.

While the two year minimum college prerequisite has been exacted by the Council for eighteen years, there are still eight states which have not revised or amended their statutes to conform, although these same states, with possibly one or two exceptions, do not license other than graduates of approved schools.

MEDICAL COURSE DURATION

The medical course in the United States in general is taught in four years of approximately thirty-two weeks each. The medical schools of the universities of Minnesota, Duke and Tennessee operate on the quarter plan, enabling the student by utilizing the summer months to complete the course in three calendar years. The medical schools of the University of Chicago permit a student to progress as rapidly as he desires. Fourteen medical schools in the United States require a year of internship or research as a part of the medical course, thereby lengthening the course to five years, the degree of Doctor of Medicine being conferred after completion of the internship. Duke University requires a two year internship. Ten schools offer only a two year course.

Five of the medical schools of Canada offer a five year course, four have a six year course including premedical subjects, and the University of Saskatchewan offers courses in the medical sciences only which are covered in two years. Four Canadian schools require an internship for graduation.

These data are included in table 1.

CURRICULUM

The medical curriculum, as outlined in the Essentials of an Acceptable Medical School, published on pages 684, consists of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year and grouped under nine headings, namely, anatomy (including embryology and histology), physiology, biochemistry, pathology, bacteriology and immunology, pharmacology, hygiene and sanitation, general medicine, general surgery, and obstetrics and gynecology. A certain percentage of hours of the whole number of hours in the courses is required in each of these groups. The Association of American Medical Colleges maintains the same standard with respect to the curriculum.

STATISTICS OF MEDICAL SCHOOLS

Table 1 pages 662 and 663, lists the medical schools in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association during 1935-1936 and contains figures regarding the premedical requirement for entrance for the session 1936-1937, length of the medical course by years enrolment by classes for the session 1935-1936, including fifth year students interning or engaged in research, number of graduates since July 1, 1935, dates of the beginning and ending of the forthcoming session, and the month until which applicants for admission to the freshman class are received. Changes in the classification that have taken place since

the publication of the educational statistics in 1935² can be noted in the footnotes at the bottom of the table and refer to those schools which are marked by asterisks preceding the name. Also contained in the footnotes are references to the fifth and sixth year enrolments and those schools which admit students at varying times during the year. Duke University and the two medical schools of the University of Chicago do not report their students by classes and in this tabulation, therefore, only the total enrolment is given.

The data presented in this table constitute the basis also for several of the subsequent tabulations. Beginning on page 686 are given historical information and essential facts concerning the schools arranged by states.

Seventy-seven institutions in the United States and ten in Canada are listed. With the exception of three, all these schools at the present time are approved by the Council. In eighty-four schools there were 6,646 freshman students enrolled, 6,060 sophomores, 5,755 juniors, 5,554 seniors, 380 fifth year and 227 sixth year students, during the session just ended. In the two medical schools of the University of Chicago and Duke University School of Medicine there were 851 students enrolled, making a total of 25,473 in the eighty-seven schools listed. In the United States there were 6,005 freshmen, 5,458 sophomores, 5,230 juniors, 5,020 seniors, and the 851 students from the schools just mentioned, a total of 22,564. The total students registered by classes in the United States was 21,713. The enrolment in the ten Canadian schools was as follows: first year, 641, second year, 602, third year, 525, fourth year, 534, fifth year, 380, and sixth year, 227, a total of 2,909. The 25,473 medical students enrolled do not include 1,213 in the United States and 124 in Canada interning as a requirement for the degree of Doctor of Medicine.

Since July 1, 1935, 5,656 received M.D. degrees, 5,183 from schools in the United States and 473 from Canadian institutions.

In addition, there were 130 part-time, 267 special and 751 graduate students studying in medical schools.

Ten medical schools had an enrolment of less than 100 students. None of the schools comprising this figure give the complete medical course. Fourteen schools matriculated fewer than 200 but more than 100, twenty-four less than 300, nineteen fewer than 400, nine less than 500 and 600, respectively. Two schools matriculated more than 600 students. The smallest enrolment (nineteen) was at the University of Mississippi School of Medicine, which for the session 1935-1936 did not offer instruction to freshmen. Not being a complete medical school, the figure given represents sophomore students only. The greatest number (853) were enrolled in the University of Toronto Faculty of Medicine, which has a six year course including premedical subjects. The corresponding high figure among schools in the United States was (637) at the University of Illinois College of Medicine. The lowest enrolment among four year colleges in the United States was (100) at Albany Medical College. This school likewise awarded M.D. degrees to the smallest group (twenty-five) since July 1, 1935. The school graduating the greatest number was Northwestern University Medical School, which awarded 160 diplomas.

The majority of schools will begin the session 1936-1937 about the middle of September and end early in June.

Of sixty-seven schools that replied to the inquiry regarding the month until which applications for admission to the first year class will be received, two replied February, ten March, seven April, six May, ten June, eight July, five August, seventeen September and one each gave October and December.

The name of the dean or administrative officer of each institution is also given in table 1.

BIRTHPLACE OF STUDENTS

In table 2, pages 664 and 665, the birth state of students in attendance in medical schools during 1935-1936 is shown by schools. The state furnishing the greatest number of students according to state of birth was New York 3,469, followed by Pennsylvania with 2,125, Illinois with 1,524 and Massachusetts with 947.

From the twelve states in which no medical schools are located there were enrolled as students the following

| | Number Enrolled | Number of Schools |
|--------------|-----------------|-------------------|
| Arizona | 37 | 19 |
| Delaware | 39 | 16 |
| Florida | 116 | 34 |
| Idaho | 94 | 33 |
| Maine | 121 | 30 |
| Montana | 79 | 32 |
| Nevada | 27 | 16 |
| New Jersey | 853 | 65 |
| New Mexico | 37 | 19 |
| Rhode Island | 146 | 36 |
| Washington | 233 | 44 |
| Wyoming | 24 | 18 |
| | 1,806 | |

There were 112 born in the United States possessions and 795 in foreign countries. In addition, 2,478 Canadians were also studying medicine, 115 of whom

TABLE 3—Students Classified by Birthplace

| State | Number of Schools | Attending School in State of Birth | Birthplace Elsewhere |
|----------------------|-------------------|------------------------------------|----------------------|
| Alabama | 1 | 49 | 63 |
| Arkansas | 1 | 195 | 94 |
| California | 4 | 360 | 696 |
| Colorado | 1 | 161 | 44 |

| Virginia | 2 | | |
| Washington | 1 | | |
| West Virginia | 2 | | |
| Wisconsin | 1 | | |
| Totals | 87 | 14,720 | 10,734 |

were matriculated in schools in the United States and 2,363 in Canadian schools.

This table is being reproduced for the second time. A similar tabulation in previous years recorded the home state or residence, of medical students. Since, however, there is no uniformity among schools or students in the meaning attached to the word residence,

an effort to ascertain whether students go to schools outside their home state to study has been made in the manner presented in this issue. Very few schools have defined the terms "resident" and "nonresident" in such a way as to make them of real value in the classification of students. Indiana and Michigan have legally defined the term.

In table 3 the classification of students is further classified by birthplace, indicating that 14,739 are study-

TABLE 4—Schools, Students, and Graduates by States*

| State | Schools | Students | Graduates |
|----------------------|---------|----------|-----------|
| Alabama | 1 | 112 | |
| Arkansas | 1 | 289 | 48 |
| California | 4 | 1,046 | 217 |
| Colorado | 1 | 205 | 50 |

* Excluding fifth or intern year students.

ing in the state of their birth and 10,734 elsewhere. This is particularly significant in Illinois, where, of the 2,340 students in five schools, 1,175 were born outside the state.

More than 800 born elsewhere are studying in Pennsylvania, while 724 in this group are in New York schools. Altogether, 42.1 per cent are studying in schools located in other than their birth state. Eliminating the 1,806 born in states having no medical school, there are still 8,928 of the total number of students, 25,473, studying outside their birth state.

A perusal of table 3 will show many instances wherein the number studying elsewhere far exceeds the number attending school in the state of birth. It also shows some states in which the contrary is the case, notably Indiana, Iowa, Minnesota, Ohio, South Carolina and Texas.

It is conceded that this tabulation does not present an absolutely true picture in that all those studying in schools located in states other than their birthplace cannot be classed as nonresidents, since they may have established their homes in other states. It is believed, however, that the table reveals a trend which may be of interest.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

The number of schools, students and graduates for each state are given in table 4. New York, with the largest number of schools, nine, naturally had the greatest number of students and graduates, 2,607 and

635 respectively Pennsylvania with six schools had 2,405 students and 588 graduates Illinois with five schools, 2,340 students and 591 graduates ranks in the third largest group In four schools in California there were 1,056 students and 217 graduates while in three schools in Massachusetts there were 1,251 students and 312 graduates Other states had fewer than 1,000 medical students and 300 graduates In the seventy-seven medical schools in the United States, including those that offer only preclinical courses, there were 22,564 students and 5,183 graduates Students interning as a requirement for the degree, or fifth year students, are not included in the figure 22,564 Also excluded are part-time, special and graduate students

REQUIRED HOSPITAL INTERNSHIPS

In tables 5 and 6 are listed the medical schools and state licensing boards now requiring internships for the M D degree and state licensure respectively Some medical schools will accept research or other clinical

work in lieu of the internship The effective date of the requirement is shown in both tables Fifteen schools in the United States and three in Canada exact the internship requisite The M D degree has been conditioned on an internship at the University of Minnesota Medical School since 1915 McGill University Faculty of Medicine has announced the reorganization of its medical curriculum into a course of five years including an internship The new plan, which goes into effect in September, will replace the present undergraduate course now spread over five academic years of seven and a half months each, by a course covering four years of nine months each The fifth year may be spent in an internship in an approved hospital or in further medical study at McGill or at another medical school approved by it

As revealed in table 6, seventeen states, Alaska and the District of Columbia require that applicants for licensure possess a hospital internship The first state exacting the internship was Pennsylvania in 1914 and the last one Vermont, affecting the graduates of 1934 and thereafter

During 1935-1936 there were 1,213 students of the United States and 124 in Canada reported as interns, a total of 1,337

Duke University School of Medicine grants the degree after the completion of the senior year, but all graduates are required to spend at least two years in hospital or laboratory work after graduation

While some of the medical schools and licensing boards may have their own list of hospitals recommended for intern training, generally the Council's list of hospitals approved for internships is followed A revised edition will be found beginning on page 693

NECROPSIES IN HOSPITALS APPROVED FOR INTERNSHIPS

Publication of the list of approved internship hospitals most successful in necropsy performance has had several salutary results In this way it is possible to assign credit to hospitals for meritorious, scientific interest and accomplishment Also it has strengthened the opinion that any hospital conducted under any aus

* Completed medical course. Internship or other acceptable clinical work is a requirement for the M.D. degree.

† Two year internship requirement after graduation.

for those schools which require the internship or other acceptable clinical work as a requirement for graduation. There were 5,491 fifth year students or graduates serving internships during the period July 1, 1935, to July 1, 1936. The number of graduates or those who completed the medical course during the period

from July 1, 1934, to July 1, 1935, was 5,611. Of this figure 120 either were not successful in securing or did not desire internships. In the Canadian schools, of the 483 graduates or intern students, 449 were serving internships and thirty-four are unaccounted for. In the United States there were 5,128 graduates or students, of whom 5,042 were interning, leaving eighty-six not serving internships during this period.

Of the 5,491 interns, 1,213 in the United States and 124 in Canada were fulfilling the intern requirement for the M.D. degree, a total of 1,337, and 4,154 of the 4,274 M.D. graduates were also interning, of whom 359 were Canadian graduates and 325 interns, and 3,915 graduates of United States schools and 3,829 interns.

With the exception of one in Canada, every school in the list has more than 90 per cent of its graduates serving internships, and in twenty-three schools 100 per cent interned. Excluding those schools that require the internship for graduation, ninety-eight per cent of all graduates here listed have this added experience.

WOMEN IN MEDICINE IN THE UNITED STATES

As shown in table 10, the number of women students has been rather constant since 1920, although in 1936 there were more than in any one year. During the past

TABLE 10—*Women in Medicine in the United States*

| Year | Women Students | Percentage of All Students | Women Graduates | Percentage of All Graduates |
|------|----------------|----------------------------|-----------------|-----------------------------|
| 1905 | 1 073 | 4.1 | 219 | 4.0 |
| 1910 | 807 | 4.0 | 116 | 2.6 |
| 1915 | 592 | 4.0 | 92 | 2.0 |

| 1933 | 1 056 | 4.7 | 214 | 4.4 |
| 1934 | 1 070 | 4.5 | 211 | 4.2 |
| 1935 | 1 077 | 4.7 | 207 | 4.1 |
| 1936 | 1 133 | 5.0 | 216 | 4.7 |

year there were 1,133 women studying medicine in the United States, fifty-eight more than last year. The percentage of women to all students for the academic year 1935-1936 was 5.0 as compared with 4.7 in 1935. There were 246 graduates, thirty-nine more than last year. Of all the women matriculants, 116 students were enrolled at the one medical college for women, while 1,017 were matriculated in sixty-seven coeducational schools. From the Woman's Medical College of Pennsylvania, thirty-three were graduated, while 213 secured their degrees from coeducational institutions.

DISTRIBUTION BY SEX

Students and graduates classified by sex are shown in table 11. There were seventy-five schools which had both men and women students in the United States and Canada, of which fifty-nine had women graduates. Altogether there were 24,219 men and 1,254 women students, and 5,388 men and 268 women graduates. There is one medical college for women, the Woman's Medical College of Pennsylvania, which had 116 students and thirty-three graduates, leaving 1,140 women students pursuing their medical education and 235 who completed the course in coeducational institutions. Of the 25,473 students enrolled in all medical schools, there were 21,431 men and 1,133 women studying in the United States, and 2,788 men and 121 women

in Canadian schools. An average of seventeen women students were enrolled in the seventy-five coeducational institutions in the United States and Canada. There was an average of four graduates from sixty schools.

PART-TIME GRADUATE AND SPECIAL STUDENTS

In fifty-four medical schools of the United States and Canada during 1935-1936 there were, in addition to the regularly enrolled students, 1,148 part-time special and graduate students pursuing medical subjects. The group consisted of 130 part-time, 267 special and 751

graduate students. The 130 part-time students were enrolled in twenty-one schools, the greatest number (thirty-one) were at Wayne University College of Medicine. The University of Minnesota Medical School had nineteen such students, while St. Louis University School of Medicine had fourteen. Of the special students, the greatest number (fifty-seven) were at Northwestern University Medical School, while Vanderbilt University School of Medicine enrolled thirty-seven and at the School of Medicine of the Division of the Biological Sciences of the University of Chicago there were twenty-three. The 267 special students represented thirty-six schools. Students pur-

sung subjects leading to higher degrees were studying in twenty-six schools. Altogether, there were 751 such, 185 of whom were at Washington University School of Medicine, seventy at Northwestern University Medical School and sixty-four at the University of Illinois College of Medicine. Both part-time, special and graduate students were studying at the University of Kansas, Johns Hopkins, New York University and Vanderbilt. Among Canadian schools nine part-time, nine special and thirty-six graduate students were enrolled. These data are included in table 12.

MED GRADUATES HOLDING DEGREES IN ARTS OR SCIENCE

From the figures contained in table 13 it can be noted that 4,195 of the 5,656 graduates of medical schools during 1935-1936 hold baccalaureate degrees in

addition to the medical degree. Figures are not available to show how many of these graduates obtained their degrees subsequent to beginning the medical course. Only five schools in the United States and Canada require a degree for admission, while one requires four

* Estimated figure

University, University of Oregon and Vanderbilt University is three years of college work, their entire graduating class for the past session hold baccalaureate degrees. The same is true of the Universities of Oklahoma and Wisconsin, which have only a two year premedical requirement. Since the Division of the Biological Sciences and the Universities of Oklahoma and Wisconsin offer the B.S. degree in Medicine during the medical course, this may account for the fact that all their graduates hold degrees. Among the eight schools that require a degree, three years of college work and a degree after the first medical year, or four years premedical training, only five report that their complete graduating class hold degrees. It may be that the prerequisite was raised in recent years.

MEDICAL SCHOOLS STUDENTS AND GRADUATES IN THE UNITED STATES 1905-1936

The number of medical schools, students and graduates in the United States for each five year period from 1905 to 1920, and for each year since, is shown in table 14. The total number of undergraduate medical students for the college session 1935-1936 was 22,564, a decrease of 324 from the preceding session. In 1905,

TABLE 14—*Schools, Students and Graduates in the United States—1905-1936*

| Year | No. Schools | Students* | Graduates |
|------|-------------|-----------|-----------|
| 1905 | 160 | 26,147 | 5,606 |
| 1910 | 131 | 21,526 | 4,440 |
| 1915 | 90 | 14,891 | 3,536 |

| 1934 | 77 | 22,729 | 5,035 |
| 1935 | 77 | 22,858 | 5,101 |
| 1936 | 77 | 22,564 | 5,183 |

* Includes figures for schools offering preclinical courses

26,147 were in attendance at the 160 medical schools then existing. This tabulation includes data for only those taking medical courses leading to the M.D. degree. They do not include part time and special students even though their work may later be accepted for the M.D. degree, since at the time they are reported as part time and special students rather than as candidates for a medical degree. Omitted from these statistics also are university graduate students majoring in the medical school but not candidates for the M.D. degree. In 1905 there were 26,147 students. The next fifteen years shows a steady decrease in enrollment, while from 1921 to 1935 there was a continuous increase. The Council a year ago issued a general warning against the admission of larger classes than can properly be accommodated or than can reasonably be expected to satisfy approved scholastic standards. Several schools immediately decreased their freshman enrollment and others have indicated adherence to the Council's principles as soon as practicable.

As shown in table 14, the total number of graduates was 5,183, an increase of eighty-two over the preceding session. With the exception of the slight decrease in the number of graduates in 1933, as compared with previous years, there has been a steady increase since 1926. As will be noted, there were marked increases

years and three admit students with three years of college work if the baccalaureate degree is conferred in absentia at the end of the first year in medicine. Thirty-one schools offer a B.S. in medicine degree at sometime during the medical course. While the entrance requirement of Stanford, the School of Medicine of the Division of the Biological Sciences of the University of Chicago, Rush Medical College, Wayne

in 1923, 1924 and 1925. In the seventy-seven recognized medical schools in the United States during 1935-1936 there were 22,564 students, including those having an incomplete medical course, and 5,183 graduates.

In this connection it is interesting to note the number enrolled in the various classes in the United States for each session from 1930-1931 to 1935-1936 inclusive, as shown in table 15. The total attendance for the first year for the session 1935-1936 was 6,005, or 351 fewer than the number enrolled for the session 1934-1935, which in turn was 101 fewer than the number enrolled in 1933-1934. The total attendance for the remainder of the classes was, respectively, 5,458, 5,230, 5,020 and 1,213. The two medical schools of the University of Chicago are not operated under the promotion by class system but on an individual plan. It is not possible, therefore, to group them into the figures given. This is likewise true of the enrolment at Duke University. They are, however, included in the totals. There were 219 students enrolled at Duke, 311 at the School of Medicine of the Division of the Biological Sciences of the University of Chicago and 321 at Rush Medical College, a total of 851. There were 344 fewer students enrolled than in 1934-1935 and 770 more than were enrolled in 1930-1931. Only one new medical school has been opened since that session, namely, the Louisiana State University Medical Center, which had an enrolment of 315 for the session of 1935-1936. Excluding the students of this university, there were 455 more students enrolled during the college session just ended than in the seventy-six medical schools that existed in 1931. For the session 1935-1936 the freshman and sophomore enrolments decreased 351 and 166 respectively, while the junior and senior year enrolment was increased by 88 and 115 students respectively, exclusive of the figures for the three schools previously mentioned in this paragraph. The intern year decreased by twenty.

The Association of American Medical Colleges³ reports that there were 34,427 applications for admission to the 1935 freshman class, representing 12,740 applicants, and of these 6,900 were accepted and 5,840 rejected. However, as already indicated 6,005 actually enrolled for the freshman year, exclusive of the University of Chicago and Duke University enrolment. It

Intern year.

may be noted that 895 were accepted by medical schools who did not enroll in a medical school in 1935-1936 because of multiple application. The College Association has ascertained from its survey that about 1 to 2 per cent of those accepted drop out within the first week or two.

NEGRO STUDENTS AND GRADUATES

Negro medical students for the session 1935-1936 are recorded by classes in table 16. Totals for the

college sessions 1934-1935 are shown for comparison. There were 369 such students and seventy-three graduates, a decrease of thirty-three students and thirty-one graduates respectively. The only medical school strictly for Negro youth, Meharry Medical College, organized in 1876, matriculated 183 students and had thirty-two graduates. At Howard University College of Medicine, organized in 1869, they compose a majority of those

in attendance and for the session 1935-1936, 133 students of a class of 142 and thirty-three of the thirty-five graduates were Negroes. These two schools graduated the majority of the Negro students. All other schools graduated a total of eight. In twenty schools in the United States, forty-five Negro students were enrolled and six were graduated. There were eight Negro students in three Canadian schools and in one there were two graduates. The enrolment by classes in all schools was first year 107, second year 98, third year 84 and fourth year 78, a total of 369. In 1934-1935 corresponding figures were 125, 90, 80 and 107, a total of 402. In 1935 there were 104 graduates and this session only 73.

FEES

In table 17 the eighty-seven medical schools of the United States and Canada have been grouped according to the tuition fees charged. To arrive at the figures listed, an average was computed of the fees for each school. Included in these fees are the various minor charges, such as for matriculation, breakage, diploma and graduation. Four schools have fees of less than \$100. These were Louisiana State University, University of North Dakota, University of Oklahoma and the University of Texas. The first three schools named, however, charge an additional fee of \$300, \$85 and \$200 for nonresidents. The University of Texas does not accept nonresidents. The eleven schools having

fees over \$500 are Yale, George Washington, Johns Hopkins, Columbia, Cornell, Long Island College, New York Medical College, New York University, Syracuse, Buffalo and the University of Pennsylvania. Thirty-one schools in the United States and three in Canada made an additional yearly charge for nonresidents ranging from \$50 by the Universities of Mississippi, Missouri, Nebraska, Cincinnati (nonresidents of Cincinnati) and Virginia to \$300 exacted by the University of California and Louisiana State University.

The lowest nonresident fee was charged by the University of Kansas (\$43 for the first year, \$62 for the second year and \$88 for the third and fourth years). No noticeable increase or decrease has been noted in the fees charged by medical schools, there being four in the group having less than a \$100 a year fee, one more than during 1934-1935, ten had fees ranging from \$100 to \$200, one less than the previous college session, the number in the group between \$200 and \$300 remained the same (twenty-six), fifteen charged between \$300 to \$400 a year, while in 1934-1935 there were sixteen in this group, from \$400 to \$500 there were twenty-one, also in last session, and in the last group, \$500 or over, there were eleven schools, one more than in 1934-1935. The fees are not listed in these statistics by individual schools other than in the descriptions beginning on page 686. Provision is made

TABLE 17—Fees 1935-1936—United States and Canada*

also by most schools for scholarships and loan funds for deserving students. The average fee charged by all schools was \$329.

INSTRUCTION IN MEDICAL SCHOOLS REGARDING ORGANIZED MEDICINE

Resolutions were presented for official consideration to the House of Delegates at the recent session in Kansas City by the medical societies of Arkansas and Ohio through the Board of Trustees of the Association reading in substance as follows:

WHEREAS It has been noted with disappointment that some of the graduates of medical schools and colleges in recent years apparently are unfamiliar with the objectives and activities of organized medicine and lack a clear understanding of the benefits to be derived through membership in local, state and national medical societies be it

Resolved By the House of Delegates of the Ohio State Medical Association Oct. 24 1935 that the administrative officials of all accredited American medical colleges be respectfully requested to provide instruction for senior students on the activities services and benefits of organized medicine be it further

Resolved That a resolution be transmitted to the dean of each of the accredited medical colleges of America the Council on Medical Education and Hospitals and the Board of Trustees of the American Medical Association and the secretary of each constituent state medical society

The Reference Committee on Reports of Board of Trustees and Secretary, to which this resolution was referred, endorsed the request of the Board of Trustees in presenting the resolutions for consideration. They are reproduced in this issue, as it contains a summary of events of the year. It is to be hoped that graduates can in some way be made familiar with the objectives and activities of organized medicine.

CITIZENS OF THE UNITED STATES ENROLLED IN MEDICAL FACULTIES ABROAD

A study of the number of citizens of the United States enrolled in medical faculties abroad will be found in table 18. This tabulation covers the academic year

* 1934-1935 figures.

** 1935-1936 figures.

1935-1936 In a few cases because figures were not available it was necessary to reproduce figures from previous sessions for several schools known to have large numbers of citizens of the United States enrolled. Including these figures there were 1,517 students and 242 graduates or those who completed their medical training in sixty-six schools. This study has been carried on since 1931, when it became evident that great numbers of Americans were going to Europe to study. The files of the Association of American Medical Colleges indicate that the application record of many of these students show that they have made application to medical schools in the United States without success. A study has also been conducted of the license record of foreign physicians.⁴ The following tabulation (representing both American and foreign born physicians) of the number examined in six years and the percentage failing is of interest:

| | Number Examined | Passed | Percentage Failed |
|------|--------------------|--------|----------------------|
| 1930 | 167 | 92 | 44.9 |
| 1931 | 158 | 91 | 42.4 |
| 1932 | 182 | 96 | 47.3 |
| 1933 | 200 | 129 | 35.5 |
| 1934 | 285 | 170 | 40.2 |
| 1935 | 437 | 302 | 30.9 |

In addition to the figures given, a number are periodically licensed in New York without examination—by endorsement of their foreign credentials, which are equivalent to licensure in this country. In 1935, sixty-nine were so registered in New York.

The increase in the number examined in 1935 represents mostly the Americans who began the study of medicine in 1930. In 1933 the Federation of State Medical Boards adopted a resolution to the effect that no student matriculating in a European medical school subsequent to the academic year of 1932-1933 will be

admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges and the Council on Medical Education and Hospitals, and graduation from a European medical school after four academic years of attendance, and further submits evidence of having satisfactorily passed the examination to obtain a license to practice medicine in the country in which the medical school from which he is graduated is located. This policy of the federation has been made effective by individual action on the part of some of the state licensing bodies and the National Board of Medical Examiners.

Two years ago the governments of several European countries sent representatives to this country to discuss appropriate standards for students from the United States. Through conferences with the officers of the Council and of the Association of American Medical Colleges a much better understanding of the problem was gained.

The enrolment of students in foreign faculties as reported for each session since 1930-1931 is shown in table 19. The largest numbers were enrolled in Austria, Germany, Italy, Scotland and Switzerland. Those enrolled in 1930-1931 will for the greater part finish or have finished their courses this year and are already presenting a problem to hospitals where they are applying for internships and to state boards for licensure. To assist hospitals, as well as to safeguard them, the Council in February 1936 passed the following resolution:

Resolved That when suitable graduates of class A schools of the United States and Canada are not available hospitals approved for intern training may accept graduates of European schools who have passed parts I and II of the examinations of the National Board of Medical Examiners.

Furthermore, the House of Delegates of the American Medical Association adopted the following resolutions at its recent meeting in Kansas City:

WHEREAS Through the initiation, support and watchfulness of organized medicine, standards of medical education and medical practice have rapidly and continuously advanced and

WHEREAS There is a serious danger of this most satisfactory state of progress being undermined and weakened by the registration to practice of graduates of medical schools of foreign countries and

WHEREAS There are at the present time more than 1,500 American students attending medical schools in foreign countries many of them not having satisfactory credentials for admission to American medical schools and

WHEREAS There is in the files of the Council on Medical Education and Hospitals of the American Medical Association, and the Federation of State Medical Boards evidence that many of the foreign medical schools do not consistently maintain and enforce the same high standards as are maintained in the medical schools of the United States therefore be it

Resolved That each applicant for medical license in the United States in order to adjust this inequality and to show a knowledge of acceptable medical practice should be required before being admitted to a written examination before a properly constituted examining board to hold a license to practice in the country of his graduation and a certificate that he has completed a year's work as an intern in a hospital approved for internship training or should complete the fourth year in an American class A medical college and be it further

Resolved That the House of Delegates of the American Medical Association approve the foregoing and that a copy be sent to the properly constituted officers of each examining board of the United States and to the Federation of State Medical Boards with the request that they consider seriously urgent need for the adoption of such rules and/or legislation necessary to put the purposes of these resolutions into effect.

It is to be hoped that licensing boards will more uniformly adopt measures to ensure that foreign graduates will be admitted to the licensing examination on the basis of a professional training which is not inferior to that required in the United States.

* Institutions offering graduate medical courses other than universities are not included in this tabulation
+ yes 0 no

plan for the establishment of standards, ratings and inspections of training schools in physical therapy be effected providing that the expense of such inspection be borne by the school requesting the same

The Board of Trustees designated the Council on Medical Education and Hospitals as the proper body to proceed in making such a survey. Inspections of thirty-five schools for physical therapy technicians were made in connection with the regular field work of the Council's staff. Complete information was secured regarding the organization, faculty, prerequisites, curriculum, physical plant, records and affiliations for each school.

In an analysis of the inspection reports the following items were of special interest:

1 *Directors of Schools*—In twenty-four schools the directors were doctors of medicine, and in the remainder academic teachers, registered nurses or physical education instructors.

2 *Prerequisite for Admission*—Thirteen schools placed their requirement at high school graduation. However, seven of these were regular college courses. In eight schools there was no minimum educational requirement, these represented mainly schools of the commercial type. Candidates having two years of physical education are admitted to four courses of training, and three schools limit their students to registered nurses.

3 *Duration*—The duration of the training varies greatly, from a few weeks in some schools to eighteen months in others. In seven instances the courses conducted by a university or college require four years. Seven schools conduct twelve-month courses of training, ten schools have nine month courses, ten schools have less than nine-month courses, and one school has courses of nine, twelve and eighteen months.

4 *Affiliations*—Affiliations for practice training exist in connection with twenty schools. General hospitals are used mainly, with special hospitals, clinics and institutions of various types in use in many instances. Fifteen of the schools have no affiliations to provide clinical material for practice training, in these schools the students either practice on one another or have no practical training at all.

5 *Number of Students*—The enrolment varies from one to twelve in thirty-two schools, the average being approximately six students. Three commercial schools reported attendances of twenty-five, fifty and one hundred students.

6 *Tuition*—Fees vary extensively. The average fee lies between \$100 and \$200 for nine and twelve month courses. Six schools require tuition fees of \$300 and one of \$400.

7 *Certification*—On satisfactory completion of the course of training, each school endorses the graduate by means of a letter of recommendation, certificate, diploma or degree, as the case may be.

The cooperation of the Council on Physical Therapy, the American Congress of Physical Therapy and the American Physiotherapy Association was secured in determining minimum education requirements for physical therapy technicians. The following "Essentials of an Acceptable School for Physical Therapy Technicians" were adopted by the Council on Medical Education and Hospitals and passed by the House of Delegates of the American Medical Association at the Kansas City meeting, May 9, 1936.

ESSENTIALS OF AN ACCEPTABLE SCHOOL FOR PHYSICAL THERAPY TECHNICIANS

I ORGANIZATION

1 A school for physical therapy technicians should be incorporated as or under a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

2 Affiliation with a college, university or medical school is highly desirable but is not an absolute requirement.

II FACULTY

3 The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough education and training and successful teaching experience. Nominations for faculty positions should be made in accordance with academic custom. The staff should include not less than one qualified salaried instructor and in each institution where practical training is carried on not less than one qualified physical therapist. The question of full time and part time appointments is not as important as the qualifications of the instructors, who should be specialists or exceptionally well trained and well qualified in the lines they are teaching.

III PLANT

4 The school should own, or enjoy the use of, buildings sufficient in size to provide adequate lecture rooms, class laboratories and administration offices. Adequate equipment should include anatomic charts, manikins, models, stereopticons and other aids to effective teaching. It is suggested that dissecting materials should be provided to enable each student to dissect or have the benefit of demonstration of dissection of at least the lateral half of the human cadaver. Skeletons and disarticulated bones should be supplied. There should be a library receiving regularly all the scientific periodicals pertaining to physical therapy, current numbers of which should be easily accessible to the students.

IV CLINICAL FACILITIES

5 Provision should be made for each student to receive practice training adequate in kind and amount under competent supervision in physical therapy in a hospital or other institution acceptable to the Council on Medical Education and Hospitals of the American Medical Association.

V RESOURCES

6 Experience has shown that a modern school of physical therapy cannot as a rule be maintained by the income from students' fees. No physical therapy school, therefore, should expect to secure approval which does not have a substantial income in addition to students' fees.

VI ADMINISTRATION

7 There should be careful and intelligent supervision of the entire school by an executive officer who, by training and experience, is fitted to interpret the prevailing standards in physical therapy education, and who is clothed with sufficient authority to carry them into effect.

8 There should be satisfactory records, showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Except for good cause, such as for illness, no credit should be given for any course when the attendance has been less than 90 per cent of the full time.

VII REQUIREMENTS FOR ADMISSION

9 Candidates for admission should be able to satisfy one of the following requirements:

- (a) Two years or sixty semester hours of college, including courses in physics and biology.
- (b) Graduation from an accredited school of nursing.
- (c) Graduation from an accredited school of physical education.

Courses in general physics, chemistry and biology are highly recommended for all who seek to enter training in physical therapy.

10 The admission of students to the physical therapy school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the physical therapy school is an integral part of the university, this work usually devolves on the university examiner.

11 Advanced standing may be granted to students for work done in other acceptable physical therapy schools or hospital departments, provided the entrance requirements and other essentials herein set forth have been complied with. Official

verification of the student's previous physical therapy work should be obtained by direct correspondence with the schools previously attended, and his preliminary qualifications should also be verified and recorded the same as for first-year students

12 Complete physical examination of each student admitted should be conducted under the auspices of the school

VIII PUBLICATIONS

13 The school should issue, at least annually, a bulletin setting forth the character of the work which it offers. Such announcement should contain a list of the members of the faculty with their respective qualifications

Suggested electives asepsis, bandaging, first aid, history of physical therapy, hygiene, joint measurements, office routine, occupational therapy, records, social service.

All subjects should be taught by qualified teachers
Length of course Not less than nine months

According to the foregoing standard the following schools have been found to comply. Several others are now in the process of making the necessary changes to fulfil the requirements.

The list of schools approved for physical therapy technicians will be maintained as a permanent part of

Schools for Physical Therapy Technicians Conforming to the Standard Adopted by the American Medical Association in 1936

the Council's work and revisions will be made from time to time. New schools will be considered for approval on application to the secretary of the Council on Medical Education and Hospitals of the American Medical Association.

The American Congress on Physical Therapy, organized in 1921, has done a great deal to advance the scientific knowledge of the specialty. In 1935, with the aid of the Council on Medical Education and Hospitals, the congress established the American Registry of Physical Therapy Technicians. The objects of the Registry among others are:

'To maintain the minimum standards of educational and technical qualifications as given by the Council on Medical Education and Hospitals of the American

Medical Association for technicians administering physical therapy in hospitals, clinics and physicians' offices

"To cooperate with the Council on Medical Education and Hospitals of the American Medical Association in its investigation, classification and periodic inspection of schools which conduct training courses for physical therapy technicians"

The American Registry of Physical Therapy Technicians has indicated that graduates from schools approved by the Council on Medical Education and Hospitals will be admitted to its examinations. The offices of the American Registry of Physical Therapy Technicians are at 30 North Michigan Avenue, Chicago, and the registrar is Miss Marion G. Smith.

SURVEY OF SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

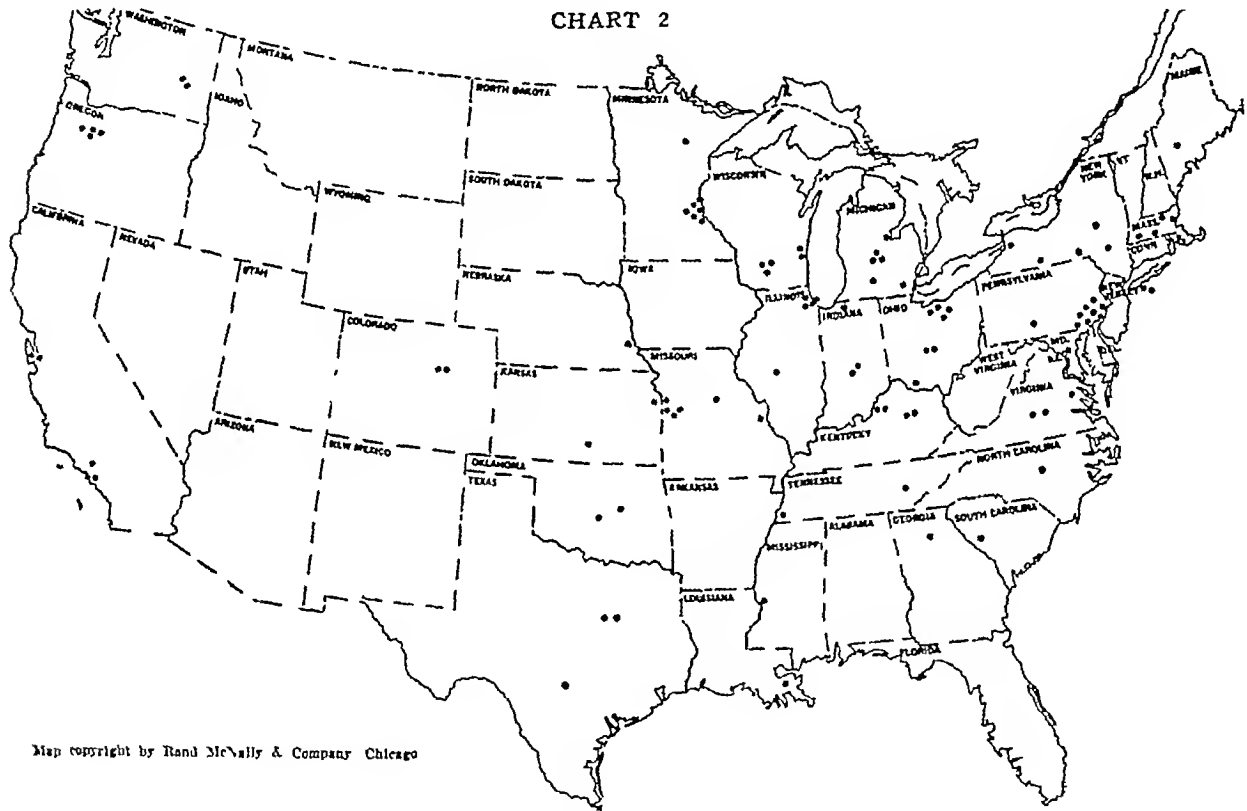

The first serious effort made to elevate the standards of education for clinical laboratory technicians was made in 1928, when the American Society of Clinical Pathologists established its Board of Registry. At first, admission to the Registry was based on credentials and recommendations. In 1933 a more accurate system of identifying those qualified for registration was instituted by placing in operation the examination system

of hospital standards, it decided to make a comprehensive survey of the situation.

One hundred and ninety-six schools have been visited by members of the Council staff. They are of three general types:

1 *The College or University Course*—Instruction in these courses is based on regular standard entrance requirements of the particular college or university and

CHART 2

Map copyright by Rand McNally & Company Chicago

Geographic distribution of schools for clinical laboratory technicians which conform to the standard adopted by the American Medical Association.

At the same time the board made a questionnaire survey of schools for laboratory technicians and set up a minimum standard for approved schools. The first list of schools published under the Board of Registry appeared in 1933.

Since the beginning of the Registry there has existed an active cooperation between the Board of Registry and the Council on Medical Education and Hospitals. Realizing the need for inspection of schools seeking approval the board in 1933 informally requested the aid of the Council in making such inspections in connection with its regular hospital survey work. Since the Council considered this training as a special type of medical education definitely related to the improve-

ments are exchangeable with other schools of the same standing. The fourth year is usually given over to instruction and practice training in a hospital laboratory department affiliated with the educational institution. As a rule, on completion of the fourth year, a Bachelor of Science Degree in Medical Technology is conferred. Several schools continue throughout the four years with didactic training incorporating such courses as bacteriology, clinical microscopy, organic chemistry, physiologic chemistry, and physiology, in lieu of a year of practice training in a hospital laboratory.

2 *Hospital Laboratory Departments Offering Courses on the Apprenticeship Basis*—This group is by far the largest. Students are admitted on one, two, three

Notes

- Regular four year course leading to a B S degree
- Postgraduate course leading to an M S or M A degree
- Charged on basis of so much per credit hour
- Students in state for year out of state students \$120 year
- Course includes twelve months x ray training
- Some accept for medical students
- Course includes six months x ray training
- Course includes four months x ray training
- Ten dollars per credit hour

Notes

- Four college chemistry and biology
- Plus and one-half year course leading to a B S degree.
- Additional Affiliations

- Multnomah Hospital Portland—300 beds 274 occupancy

or four years of college training, including basic sciences or graduation from an accredited nursing school. The work is not highly organized, as the majority of the schools have from two to four students enrolled each year. Students attend lectures with nurses or separately. Text assignments, demonstrations and examinations are regularly scheduled.

3 Commercial Schools—The large tuition fees always required by commercial schools constitute the main admission requirement. Students are recruited through extravagant advertising in newspapers and magazines or by a series of follow-up letters, which are often so worded as to imply that employment is secured for graduates at attractive salaries. Since such schools depend on a continuous and expensive campaign of advertising, they are tempted to admit whatever candidates apply regardless of adequate preparation. For the same reason, there is a tendency to admit students whenever they apply. The Council's continuous contact with hospital laboratories and pathologists throughout the country has provided incontrovertible evidence that graduates of commercial schools are not as a class the most desirable.

The survey of schools included twenty-six universities and colleges, 149 hospital laboratory schools, twelve independent laboratories and nine schools of commercial type, operating independently of hospitals or educational institutions. The inspection reports include the following data: organization, teaching staff, clinical facilities, physical equipment, records, entrance requirements, curriculum, library and affiliations. Copies of these reports have been supplied to the Board of Registry for its use in evaluating the training provided by the various schools.

After a careful study of the data gathered in the survey, minimum standards for the approval of schools for clinical laboratory technicians were formulated. It was mutually agreed in conference with members of the Board of Registry that the Council on Medical Education and Hospitals would maintain a list of approved schools for clinical laboratory technicians in operation throughout the United States and would maintain a continuous contact with and inspection of such approved schools.

The essentials were adopted by the Council on May 10, 1936, and after having been approved by the Board of Registry of the American Society of Clinical Pathologists were passed on by the House of Delegates at the Kansas City session May 11-15, 1936. It will be noted that these essentials do not differ greatly from those formerly adopted by the Board of Registry.

ESSENTIALS OF AN ACCEPTABLE SCHOOL FOR CLINICAL LABORATORY TECHNICIANS

I ORGANIZATION

1 Acceptable schools for training laboratory technicians may be conducted by general hospitals, colleges or universities. Consideration may be given to courses operated by public health laboratories or by pathologists.

2 Responsibility for courses in hospitals should be placed on the hospital administration rather than the laboratory director. In colleges and universities this responsibility is on the controlling board as for other courses.

3 Resources for continued operation of the school should be insured through regular budgets, gifts or endowments, but not entirely through students' tuition fees. Experience has shown

that commercial schools operated for profit frequently do not adhere to proper ethical and educational standards and are, as a rule, not considered acceptable.

4 There must be available transcripts of high school, college work and other credentials. Attendance and grades of students shall be carefully recorded, by means of which an exact knowledge may be obtained regarding each student's work.

II FACULTY

5 The school should have a competent teaching staff. The director must be a graduate in medicine and a pathologist or clinical pathologist of recognized ability. He shall take part in and be responsible for the actual conduct of the training course. He shall be in daily attendance for sufficient time to supervise properly the laboratory work and teaching.

6 In laboratory practice the enrollment shall not exceed one student to each member of the teaching staff. The staff should include not less than one salaried instructor who is a registered technician or eligible for registration, in addition to the laboratory director.

III CLINICAL FACILITIES

7 Each student should receive practice training adequate in kind and amount, under competent supervision, in a hospital laboratory. The hospital should be registered by and be otherwise acceptable to the Council on Medical Education and Hospitals of the American Medical Association and have a minimum of 2000 yearly admissions.

8 Adequate space, light and modern equipment shall be provided in the laboratory department. A library containing up-to-date references, texts and scientific periodicals pertaining to clinical laboratory work and pathology should be maintained.

9 Satisfactory record systems shall be provided for all work carried on in the department. Monthly and annual classifications of the work of the department should be prepared.

IV CURRICULUM

10 A Candidates for admission should be able to satisfy one of the following requirements:

1 One year of college work, including chemistry and biology from a recognized college or university. Jan. 1, 1938, this requirement is to be raised to two years of college work.

2 Graduation from a school of nursing recognized by the state board of nurse examiners, and in addition college chemistry.

B The course of training shall be not less than twelve months in duration and shall include the following divisions:

- 1 Biochemistry
- 2 Hematology
- 3 Bacteriology
- 4 Parasitology
- 5 Histologic technique
- 6 Serology

The instruction shall include:

- 1 Text assignments
- 2 Lectures
- 3 Demonstrations
- 4 Quizzes
- 5 Examinations—written, oral and practical

V ETHICS

11 Exorbitant fees and commercial advertising shall be considered unethical.

12 Schools conducted for the purpose of substituting students for paid technicians will not be considered for approval.

The Board of Registry to which full credit must be given for the splendid pioneering work in this field is made up of six members, two of whom are elected annually by the American Society of Clinical Pathologists.

gists and serve for a term of three years. The following members comprise the present board: Philip Hillkowitz, M D, chairman, Denver; Kano Ikeda, M D, secretary, St. Paul; Israel Davidsohn, M D, Chicago; H. H. Foskett, M D, Portland, Ore.; Roy R. Kracke, M D, Atlanta, Ga.; and Asher Yaguda, M D, Newark, N. J.

According to the Registry, over 3,500 members were enrolled June 1, 1936. This number approximates one third of the clinical laboratory technicians in the United States and Canada.

Applicants for registration may secure blanks and information from the registrar, Mrs. Anna R. Scott, 234 Metropolitan Building, Denver, Colorado.

ESSENTIALS OF AN ACCEPTABLE SCHOOL OF OCCUPATIONAL THERAPY

I ORGANIZATION

1 A school of occupational therapy should be incorporated under the laws regulating associations which are operated not for profit. The control should be vested in a board of trustees rather than an individual. This board should be composed of public spirited men or women receiving no financial benefits from the operations of the schools. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, this fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

2 Affiliation with a college, university or medical school is highly desirable but is not an absolute requirement.

3 Schools of occupational therapy should not be operated by hospitals independently. It is understood, however, that hospitals are needed for practice training and especially for graduate training in the special branches of occupational therapy.

II FACULTY

1 The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough education and training and successful teaching experience. Nominations for faculty positions should be made in accordance with academic custom. The staff should include not less than one regular salaried instructor and one registered occupational therapist. The question of full time and part time appointments is not as important as the qualifications of the instructors, who should be specialists or exceptionally well trained and well qualified in the lines they are teaching.

III PLANT

1 The school should own, or enjoy the use of, buildings sufficient in size to provide adequate lecture rooms, class laboratories and administration offices. Equipment should be adequate for teaching and training. Anatomic charts, manikins and dummies should also be provided. There should be a library receiving regularly all the leading periodicals pertaining to occupational therapy, current numbers of which should be easily accessible to the students.

IV ADMINISTRATION

1 *Supervision*—There should be careful and intelligent supervision of the entire school by the dean, director or other executive officer, who, by training and experience, is fitted to interpret the prevailing standards and who is clothed with sufficient authority to carry them into effect.

2 *Records*—There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Schools should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause, no credit should be given for any course when attendance has been less than 80 per cent.

3 *Credentials*—The admission of students to the occupational therapy school must be in the hands of a responsible committee or examiner whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the occupational therapy school is an integral part of the university, this work usually devolves on the examiner or registrar.

4 *Advanced Standing*—At the discretion of the administration, advanced standing may be granted for work required in the occupational therapy curriculum which has been done in other accredited institutions. Official verification of previous work should be obtained by direct correspondence. Preliminary qualifications should also be verified and recorded.

5 *Number of Students*—The number of students admitted to the training course should not be excessive. In practical work of a laboratory nature the number of students that can be adequately supervised by a single instructor is, in general experience, about fifteen; in lectures the number may be much larger. A close personal contact between students and members of the teaching staff is essential.

6 *Discipline*—All training schools reserve the right to drop a student at any time for any cause which the school authorities deem sufficient.

7 *Publications*—The school should issue, at least biennially, a bulletin setting forth the character of the work which it offers. Such an announcement should contain a list of the members of the faculty with their respective qualifications.

V PREREQUISITES FOR ADMISSION

Requirements for admission should be:

1 *Age*—The admission of candidates should be governed by the fact that it is required that each student be not less than 21 years old at graduation.

2 *Education*—All candidates must furnish proof of having completed a high school education or its equivalent. In addition, it is desirable that all candidates, except those for the degree course, shall have had at least one year, and preferably two years, of further education or successful experience in college, art school, social service, nurse's training or the commercial field.

Candidates for admission to a training course in a college or university which is combined with work leading to a bachelor's degree should be required to comply with the regular entrance requirements of the institution concerned.

3 *Character*—All candidates should be required to present evidence of good character and general fitness, the evidence of which should be investigated and duly weighed by the school concerned.

4 *Health*—All students should be given a physical examination under the supervision of the school as soon as practicable after admission, and this examination should be repeated annually. The first examination, at least, should include a roentgen examination of the chest.

VI CURRICULUM

1 *Length of Course*—The minimum length of the course should be twenty-five calendar months (100 weeks) of full time training. The course should include not less than sixteen months (sixty-four weeks) of theoretical and technical work, and not less than nine months (thirty-six weeks) hospital practice-training under competent supervision, all as set forth in detail in succeeding sections.

2 *Distribution of Time*—The two years devoted to theoretical training should include not less than sixty semester hours, of which not less than thirty semester hours should consist of systematic instruction and not less than twenty-five hours of laboratory procedures. In special cases a variation of 10 per cent is permissible.

a The hours devoted to theoretical training should be still further subdivided as follows

| (1) Biologic Sciences include | Semester Hours |
|--|----------------|
| Anatomy Physiology Neurology Kinesiology Psychology Psychiatry | 15 |
| (2) Social Sciences | 4 |
| (3) Theory of Occupational Therapy | 4 |
| (4) Clinical Subjects include | |
| Orthopedics Tuberculosis Cardiac Diseases Blindness and Deafness Contagious Diseases (including Bacteriology if this subject is not given elsewhere) General Medical and Surgical Conditions | 4 |
| (5) Electives | 3 |
| Total | 30 |

b Practical work in the various occupations should be allotted not less than twenty-five semester hours. The following subjects should be covered

| | |
|-------------------------------------|--|
| Design Textiles Wood Metal | Leather Plastic Arts Recreation Miscellaneous |
|-------------------------------------|--|

c. The time devoted to hospital practice training shall be not less than nine months spent in the following types of hospitals

| | |
|--|--------------------------|
| Mental Hospitals | Not less than two months |
| Tuberculosis Hospitals and Sanatoriums | Not less than one month |
| General Hospitals | Not less than one month |
| Children's Hospitals or Services | Not less than one month |
| Orthopedic Hospitals or Services | Not less than one month |

The remaining three months optional

3 The curriculum outlined above should be in effect not later than Jan 1, 1939

ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL

I ORGANIZATION

A medical school should be incorporated as a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

II ADMINISTRATION

There should be careful and intelligent supervision of the entire school by the dean or other executive officer who by training and experience, is fitted to interpret the prevailing standards in medical education, and who is clothed with sufficient authority to carry them into effect.

There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of students at the teaching hospitals and dispensaries and the maternity and post-mortem cases attended.

The school should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause such as for illness, no credit should be given for any course when the attendance has been less than 80 per cent of the full time.

The school should issue, at least annually, a bulletin setting forth the character of the work which it offers. Such announcement should contain a list of the members of the faculty with their respective qualifications. The courses available should be set forth by departments (anatomy, physiology, etc.) showing for each course its number, subject, content, character (lecture, recitation, laboratory or clinic), length of time when where and by whom given and the amount of credit allowed. Information should be given regarding entrance requirements and tuition fees. The names of the students enrolled during the current or previous sessions should also be included.

The number of students to whom an adequate medical education can be given by a college is related approximately to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff. A close personal contact between students and members of the teaching staff results in an efficiency which is not possible in an institution where the number of students is excessive.

Advanced standing may be granted to students for work done in other acceptable medical schools and in granting advanced standing there should be no discrimination against

the school's full course students. Official verification of the student's previous medical work should be obtained by direct correspondence with the schools previously attended, and his preliminary qualifications should also be verified and recorded the same as for freshmen students.

The admission of students to the medical school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the medical school is an integral part of the university, this work usually devolves on the university examiner. Unless the university examiner and his records are closely accessible, however, some officer at the medical school should obtain and keep on file documentary evidence of each student's preliminary education, including both high school and collegiate work. The records must show especially that the required amount of work in the premedical sciences, including laboratory experiments, has been completed.

III FACULTY

The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough training, successful teaching experience, ability in research, and willingness to pursue an academic career. In the clinical departments this does not exclude men who are in the active practice of medicine and surgery. Nominations for faculty positions should originate in the faculty, usually being made by the dean in consultation with the department heads or a committee of the faculty. Reasonable security of tenure must be assured in order that the personnel of the faculty may have adequate stability. In the preclinical sciences the faculty should include at least ten qualified persons of professional rank¹ devoting their entire time to teaching and to that research without which they cannot well keep up with the rapid progress of medical science. For each twenty-five students in a class there should be at least one full-time assistant in each of the preclinical departments. Salaries should be sufficient to enable members of the faculty to support themselves and their families without the necessity of devoting time and energy to other occupations.

IV PLANT

The school should own or enjoy the assured use of, modern fireproof buildings sufficient in size to provide lecture rooms, class laboratories, small laboratories for the members of the teaching staff and advanced students, administrative offices and a medical library. Equipment should be adequate both for student use and for research. A trained librarian should be employed to supervise the operation and development of the library which should include the more modern text and

¹ Professorial rank as here used includes professors, associate professors and assistant professors.

reference books with the *Quarterly Cumulative Index Medicus*, the *Index Catalogue of the Library of the Surgeon-General's Office* and serviceable card indexes. The library should receive regularly all of the leading medical periodicals, the current numbers of which should be in racks or on tables easily accessible to the students. At the end of each year these periodicals should be bound and added to the files of bound periodicals.

There should be a medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that they may be easily found and employed for teaching purposes. With each pathologic specimen coming from postmortems there should also be kept the record of the postmortem, the clinical history of the patient on whom the necropsy was held, and microscopic slides showing the minute structure of the disease shown in the gross specimen. The museum furnishes an excellent means of correlating the work of the department of pathology with that of the clinical departments.

There should be sufficient dissecting material to enable each student to dissect at least the lateral half of the human cadaver, to provide cross-sections and other demonstration material and to allow a thorough course for each senior in operative surgery on the cadaver.

For experimental laboratory work, as well as for medical research, a supply of animals is essential. Proper provision is necessary also for the housing and care of such animals. In any use made of animals every precaution should be taken to prevent suffering, and work by students should be carefully supervised.

Each school should have such useful auxiliary apparatus as stereopticons, reflectoscopes, microprojectors, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, roentgen-ray apparatus, and other aids to effective teaching.

V CLINICAL FACILITIES

The school may own or control a general hospital. By control is meant the unquestioned right to appoint the attending staff. In this event the students come into close and extended contact with patients under adequate supervision. In the event that a medical school depends for clinical teaching on an independent hospital, it is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff. Such hospitals should be in close proximity to the school and have a daily average of not less than 200 patients who can be utilized for clinical teaching, these patients to be of such character as to permit the students to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties. In the use of this material, bedside and ward clinics should be developed for sections of from five to ten students, and patients in medicine, surgery and the specialties should be assigned to each student under a well supervised clinical clerk system. The treatment and care of these patients should be particularly observed and recorded by the student under the strict supervision of the intern, the resident or the attending staff of the hospital. The use of existing municipal or state hospitals for teaching purposes is also advised.

The school should also own or control ample hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

The school should own or control a well ordered dispensary or outpatient department with a daily average attendance of at least 100 patients (visits). Good histories and records of the patients should be kept and the material used in medical instruction. The attending staff should be drawn largely from the faculty, including those of highest rank.

At least fifteen maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the clinical instructor. A carefully prepared report of each case should be handed in by the student.

Facilities should be provided for at least fifty necropsies during each school session which are attended and participated in

by students. These should be performed by the professor of pathology or a member of his staff. The material thus secured should be used in connection with clinical pathologic conferences.

VI RESOURCES

Experience has shown that modern medicine cannot be acceptably taught by a school which depends solely on the income from students' fees. No medical school, therefore, should expect to secure approval which does not have a substantial income in addition to students' fees. This statement carries double weight if the school finds it necessary to maintain its own teaching hospital.

VII REQUIREMENTS FOR ADMISSION

1 The minimum of collegiate credit required for entrance to approved medical schools shall be not less than two full academic years, which shall include English, theoretical and practical courses in physics and biology, and general and organic chemistry, completed in institutions approved by accrediting agencies acceptable to the Council.

2 Admission to approved medical schools may also be by examination under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects.

A list of colleges of arts and sciences approved by the various national and regional standardizing agencies has been prepared by the Council for the guidance of medical schools in the selection of students. Exception may be made in that any school may admit applicants who have fulfilled the requirement in American or Canadian institutions not approved by such accrediting agencies, provided the applicant gives evidence of superior ability.

All collegiate instruction given in satisfaction of this requirement must be based on the same entrance requirements and must be of the same quality and standard of instruction as that required for a baccalaureate degree in the institution in which the candidate receives his preparation.

VIII. CURRICULUM

The entire course of four years shall consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours per year, and shall be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

| | |
|--|------------|
| 1 Anatomy including Embryology and Histology | 14 — 18½ % |
| 2 Physiology | 4½ — 6 % |
| 3 Biochemistry | 3½ — 4½ % |
| 4 Pathology, Bacteriology and Immunology | 10 — 13 % |
| 5 Pharmacology | 4 — 5 % |
| 6 Hygiene and Sanitation | 3 — 4 % |
| 7 General Medicine | 20 — 26½ % |
| Neurology and Psychiatry | |
| Pediatrics | |
| Dermatology and Syphilis | |
| 8 General Surgery | 13 — 17½ % |
| Orthopedic Surgery | |
| Urology | |
| Ophthalmology | |
| Otolaryngology | |
| Roentgenology | |
| 9 Obstetrics and Gynecology | 4 — 5 % |
| Total | 76 — 100 % |
| Electives | 24 — 0 % |

When the teaching conditions demand it, a subject may be transferred from one division to another.

Several of the medical schools now require an internship for graduation. Where it is not obligatory it is strongly urged and graduates should be assisted in securing internships in hospitals approved by the Council on Medical Education and Hospitals of the American Medical Association.

DESCRIPTION OF MEDICAL COLLEGES

ALABAMA

University

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE.—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868 inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are ninety semester hours of collegiate work. The course of study covers two years of thirty six weeks each. The faculty includes 14 professors and 13 instructors assistants etc. a total of 27. The tuition fees are \$271 each year. Each class is limited to fifty students. Total registration for 1935 1936 was 112. The next session begins Sept 9 1936 and ends May 26 1937. The Dean is Stuart Graves M D.

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE 300 West Markham Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 29 professors and 65 lecturers and assistants total 94. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B S degree in medicine is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$230 nonresidents are charged \$150 additional each year. The total registration for 1935 1936 was 239 graduates 48. The next session begins Sept 30 1936 and ends June 7 1937. The Dean is Frank Vinson M D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL University Campus Berkeley Medical Center, San Francisco.—Organized in 1862 as the Toland Medical College. The first class graduated in 1864. In 1872 it became the Medical Department of the University of California. In 1909 by legislative enactment the College of Medicine of the University of Southern California at Los Angeles became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work is required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 130 professors and 256 associates and assistants a total of 386. The course covers four years of eight months each and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years respectively for residents of California are \$277 \$240 \$235 and \$235 nonresidents are charged \$300 additional each year. Total registration for 1935 1936 was 238 graduates 57. The next session begins Aug 24 1936 and ends May 22 1937. The Dean is W. Melvin Marriott M D. San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of 59 professors and 240 associates assistants and instructors a total of 299. The course covers a period of five years including one year of internship. During the second year the students are in school twelve months. This is accomplished by means of the cooperative plan the student spending alternate months in an approved hospital in practical lines of medical training. The first third and fourth years each cover ten months of continuous school work. Sixty four semester hours of collegiate work are required for admission. The total fees for the four years respectively are \$470 \$375 \$485 and \$475. The total registration for 1935 1936 was 394 graduates 85. The next session begins Sept. 1 1936 and ends June 13 1937. The Dean is E. H. Risley M D. Loma Linda California and the Associate Dean is W. E. Macpherson M D. Los Angeles California.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE 3551 University Avenue.—Organized in 1888 as the University of Southern California College of Medicine. First class graduated in 1888. In 1903 it became the Medical Department of the University of California at Los Angeles. In 1909 the College of Physicians and Surgeons established in 1904 became the Medical Department of the University of Southern California. Its activities were suspended in 1920 reorganized in May 1924 under present name. The faculty consists of 144 professors and 135 instructors assistants and others a total of 279. An

internship is required for graduation. Three years of collegiate work is required for admission. Coeducational since organization. Annual fees amount to \$450. The total registration for 1935 1936 was 190 graduates 30. The next session begins Sept 21 1936, and ends June 5 1937. The Dean is Paul S. McKibben Ph D.

San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE 2398 Sacramento Street San Francisco.—Organized in 1908 when, by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 103 professors and 156 lecturers assistants and others a total of 264. Three years of collegiate work is required for admission. The course covers four years of eight and one-half months each plus a fifth year of intern work. The fees for the four years respectively are \$470, \$446, \$364 and \$364. The total registration for 1935 1936 was 234 graduates 45. The next session begins Sept 29 1936 and ends June 9 1937. The Dean is Loren Roscoe Chandler, M D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan 1 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers instructors and assistants a total of 187. The course covers four years of nine months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado for each of the four years are respectively \$253 \$243 \$223 and \$233. Nonresidents are charged \$165 additional each year. The total registration for 1935 1936 was 205 graduates 50. The next session begins Sept 28 1936 and ends June 14 1937. The Dean is Maurice H. Rees M D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812 instruction began in 1813 first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884 the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887 Yale College became Yale University. Coeducational since 1916. The faculty consists of 130 professors and 229 lecturers and assistants a total of 359. The requirements for admission are three years of collegiate work. The course covers four years of nine months each. The fees for the four years respectively are \$505, \$500, \$500 and \$520. The total registration for 1935 1936 was 206 graduates, 44. The next session begins Sept. 28 1936 and ends June 16 1937. The Dean is Stanhope Bayne Jones, M D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE 3900 Reservoir Road N W.—Organized 1851. First class graduated in 1852. The faculty is composed of 57 professors 43 associate professors 19 assistant professors and 118 instructors total 237. Required for admission three years of collegiate work. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions respectively are \$465 \$460 \$410 and \$450. The total registration for 1935 1936 was 474 graduates 134. The next session begins Sept 21 1936 and ends June 14 1937. The Dean is David V. McCauley S. J. Ph D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 11th Street N W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except 1834 to 1838 and 1861 to 1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904 by an act of Congress the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 55 professors and 115 instructors demonstrators and assistants a total of 170. Two years of collegiate work is required for admission. The course covers four years of thirty two weeks each. The fees for the four years respectively are \$550 \$500 \$500 and \$500. The total registration for 1935 1936 was 258 graduates 69. The next session begins Sept 23 1936 and ends June 6 1937. The Dean is Earl B. McKinley M D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE Fifth and W Streets N W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Twenty students comprise a majority of those in attendance. The faculty comprises 29 professors and 84 lecturers and assistants 113 in all. The admission requirements are at least two years of collegiate work. The course covers four years of thirty three weeks each. The fees for each of the four sessions respectively are \$269, \$269, \$259 and \$266. Registration for 1935 1936 was 142 graduates 35. The next session begins Sept 26 1936 and ends June 11 1937. The Dean is Numa P. G. Adams M D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE 50 Armstrong Street and Druid Hills—Organized in 1854 as the Atlanta School of Medicine. Classes graduated 1855 to 1861 when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878) taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905) reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915 assumed present title in 1917. Two years of collegiate work is required for admission. The faculty consists of 18 professors and 177 associates and assistants, a total of 195. The course of study is four years of thirty-two weeks each. The fees for each of the four years are \$300. Total registration for 1935-1936 was 223 graduates 53. The next session begins Sept. 28 1936 and ends June 7 1937. The Dean is Russell H. Oppenheimer M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place—Organized in 1828 as the Medical Academy of Georgia the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia the name being changed July 1 1933 to University of Georgia School of Medicine. Property transferred to university in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 50 professors and 35 assistants 85 in all. Three years of collegiate work is required for admission. The course is four years of thirty-four weeks each. The fees for each of the four years are \$185 for residents of Georgia and \$365 each year for nonresidents. The total registration for 1935-1936 was 148 graduates 37. The next session begins Sept. 23 1936 and ends June 7 1937. The Dean is G. Lombard Kelly M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE 706 South Lincoln Street—Incorporated in 1915 as the Bennett Medical College and operated as an organic part of Loyola University by virtue of an agreement entered into with the trustees of Bennett Medical College. Present title assumed in 1917. The Chicago College of Medicine and Surgery was purchased in 1917. The first class graduated in 1916. Coeducational. Three years of collegiate work is required for admission. The course of study is five years including an internship. The B.S. degree in medicine is conferred at the end of the third year. The faculty is composed of 138 in professorial rank and 163 others a total of 301. The fees for each year are \$371 \$407 \$336 and \$298 respectively. The total enrollment for 1935-1936 was 507 graduates 98. The next session begins Sept. 28 1936 and ends June 12 1937. The Dean is Louis D. Moorhead M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891 when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 129 professors 303 associates and instructors a total of 432. The requirement for admission is three years of collegiate work. The B.S. degree in medicine may be conferred before the end of the senior year. The course covers four years of eight and one-half months each and a fifth year spent in an approved hospital as an intern or in other practical work. The total fees are \$365 each year. The total registration for 1935-1936 was 564 graduates 160. The next session begins Sept. 29 1936 and ends June 12 1937. The Dean is Irving S. Cutter M.D.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE 1853 West Polk Street—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was canceled in June 1912 and was restored in March 1913 when the present title was assumed. Coeducational since 1898. Two years of collegiate work is required for admission. The curriculum covers four years of thirty-two weeks each and a year of internship in an approved hospital. The B.S. degree in medicine is conferred at the end of the second year. The faculty is composed of 118 of professorial rank and 249 associates instructors and assistants a total of 367. The tuition is \$150 a year for students who are residents of Illinois \$225 a year for nonresident students. The total registration for 1935-1936 was 637 graduates 144. The next session begins Sept. 28 1936 and ends June 11 1937. The Dean is David John Davis M.D.

THE UNIVERSITY OF CHICAGO MEDICAL SCHOOLS—The Medical Schools include (a) The School of Medicine of the Division of Biological Sciences and (b) Rush Medical College, both of which are organized within the Division of Biological Sciences. The first two years of the medical course for both are given in the School of Medicine of the Division of Biological Sciences on the University Quadrangles and the last two years are given either in the School of Medicine on the University Quadrangles or in Rush Medical College on the West Side.

The School of Medicine of the Division of Biological Sciences Fifty Ninth Street and Ellis Avenue—Organized in 1924. The work of the first two years of the medical course has been given on the Quadrangles since 1899 in cooperation with Rush Medical College and that of the third and fourth clinical years has been given since 1924 with the

organization of this medical school and the construction on the Quad ranges of the University hospitals and clinics. Coeducational. The faculty is composed of 98 professors 132 associates instructors and others a total of 230. The requirements for admission are three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The curriculum covers twelve quarters of work. Students are admitted at the beginning of the autumn quarter. The tuition fee for each of the four years is \$450. Total registration for 1935-1936 was 311 graduates 40. The next session begins Oct. 1 1936 and ends June 16 1937.

Rush Medical College 1758 West Harrison Street—Chartered in 1837 held first class in 1843. First class graduated in 1844. In 1887 the college became the medical department of Lake Forest University retaining however its self government. This relation was dissolved in April 1898 and in the same month affiliation with the University of Chicago was established. Coeducational since 1898. Since that time the work of the first two years has been given on the University Quadrangles. In May 1924 by a new contract the University of Chicago took over the work of Rush Medical College as a department of the University. Thereafter only clinical work has been offered by Rush Medical College. Since 1914 the course has included a fifth year consisting of a hospital internship or of a fellowship in one of the departments. Three years of collegiate work is required for admission. The year is divided into four quarters of twelve weeks each the completion of the work of three of these quarters gives credit for a college year. The next session begins Sept. 15, 1936, and ends May 31, 1937. The Dean is P. C. Dagneau, M.D.

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon—Organized in 1926. Coeducational. Offers the first two years of the medical course. Students require three more years of medicine for graduation. Two years of collegiate work is required for admission. The B.S. degree in medicine is conferred at the end of the second year. The medical faculty includes 7 professors and 3 lecturers and assistants a total of 10. The fees are \$150 for each year. The total registration for 1935-1936 was 51. The next session begins Sept. 25, 1936, and ends May 14, 1937. The Dean is W. S. Linday, M.B.

HOSPITALS APPROVED FOR TRAINING INTERNS

The following general hospitals containing 216 494 beds are considered in position to furnish acceptable internships for medical graduates

HOSPITALS, 705 INTERNSHIPS, 6,759

The terms used in the column 'Type of Internship' are defined as follows:
1 Rotating internships include services in medicine surgery pediatrics obstetrics and in the clinical and x ray laboratories

2 Straight internships are limited to a single field
3 Mixed internships are those comprising more than one service but which do not include all of the six branches which constitute a rotating internship

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an Internship in Canada, the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Department of Hospital Service of the Canadian Medical Association should be regarded as giving an Internship equivalent in educational value to that offered by hospitals in the United States approved for Intern training by the Council. It is understood however that this statement applies only to hospitals that are unqualifiedly approved under the Canadian plan and does not apply to that group referred to as "Recommended."

The following list of hospitals revised to June 1 1936, has been furnished by the Department of Hospital Service

| Name of Hospital | Location | Name of Hospital | Location | Name of Hospital | Location |

HOSPITALS APPROVED FOR RESIDENCIES IN SPECIALTIES

Note—The following hospitals are considered in position to furnish acceptable residencies in the several specialties designated for graduates who have already had a general internship or its equivalent in practice. Statistical material is based on reports received for the calendar year 1935. Reported salaries and length of appointment should be verified through correspondence with individual hospitals.

TECHNICIANS

When the Council on Medical Education and Hospitals first began its work in 1905, the place of the technician in medicine was not significant. Today there are technicians of many varieties. A partial list includes clinical laboratory technicians, x-ray technicians, occupational therapy technicians, physical therapy technicians, hydrotherapy technicians, dietetic technicians, anesthetic technicians, dental technicians and many others. These professions, auxiliary to the practice of medicine, have grown up as the need for their services became apparent. Obviously their growth was uncontrolled and unstandardized since the exact need had not in itself been defined and since the new technical discoveries on which their services depend had not yet been even partially developed. Now, however, the significance of these auxiliary professions is becoming apparent. For that reason the Council on Medical Education and Hospitals in response to resolutions coming through the House of Delegates of the American Medical Association has undertaken an investigation of the available schools in the fields of physical therapy, occupational therapy and laboratory service and has set up certain minimum standards of education to guide students who wish to affiliate themselves with medicine in these fields. The standards for such schools are listed in this issue of THE JOURNAL.

There seem now to be available thirteen schools for physical therapy technicians which conform to the standards adopted by the American Medical Association. In its survey the Council inspected thirty-five schools and received complete information concerning their organization, faculty, prerequisites, curriculum, physical plant, records and affiliations. In the work the American Congress on Physical Therapy and the American Physiotherapy Association cooperated.

One hundred and ninety-six schools for the training of clinical laboratory technicians were visited by the investigators of the Council on Medical Education and Hospitals, and ninety-six of these schools were found to conform to the standards adopted by the American Medical Association. The American Society of Clin-

ical Pathologists did the pioneering work in this field and lent its assistance to the Council in this study of schools for clinical laboratory technicians. The number of students in such schools varied from none in some of the schools that were found acceptable to 182 in the University of Minnesota. Incidentally, the next larger schools after the University of Minnesota boasted of thirty, twenty-three, and twenty-one students respectively. In all, there are ten universities and colleges which have established courses with a graded curriculum covering four years and leading to a university degree.

In the field of occupational therapy the Council has set up the essentials of an acceptable school and has investigated a considerable number of institutions. However, the specialty is in itself so new and the schools thus far on such an experimental basis that the Council has set Jan. 1, 1939, as the date on which such schools shall have set up an acceptable standard and curriculum before providing a list of acceptable schools.

Today medicine consists not of one profession but of many professions. In addition to the 155,000 physicians licensed to practice there are well nigh 1,500,000 people engaged in full time service for health and for the sick. In a profession closely allied to the welfare of mankind, greatly concerned with the safety and health of human beings, there must be minimum standards of education, morals and practice. In accepting these new responsibilities, the Council on Medical Education and Hospitals continues to render an efficient and useful service for the advancement of medicine and the welfare of the public.

STATUS OF VACCINATION AGAINST POLIOMYELITIS

Since the introduction more than a year ago of two poliomyelitis vaccines,¹ nearly 20,000 persons have received one or more inoculations of these monkey spinal cord preparations bearing the virus. Similar vaccines were tested in the laboratory by several groups during the previous two decades. Killed and partially attenuated virus was employed without demonstration of an adequate immunity in more than a certain percentage of experimental monkeys. Among the methods used to "attenuate" the virus, phenol, formaldehyde, desiccation, heating below the thermal death point of the virus and dilution were tried. Virus adsorbed to alumina gel and incorporated in olive oil and agar were tested in the hope that prolonged contact with the host might increase the quantity of antibody production. Neutralizing antibodies were produced in nearly all these attempts, but few animals resisted intracerebral or intranasal application of virulent virus as an

immunity test² Indeed, in the hands of most workers a certain number developed paralysis in the course of vaccination whenever the immunizing preparations contained living virus. None of these early investigators ventured to apply their results to man. These facts apply as well to virus mixed with sodium ricinoleate, since McKinley and Larson³ have shown that one of four monkeys succumbed to the disease during immunization.

Flexner⁴ and many others warned that there was no precedent in the assumption that a poliomyelitis virus adapted to animals for many generations was less virulent for man, the original host, although this seemed to be the case with other viruses (vaccinia, rabies, psittacosis). Since it was known that experimental monkeys developed the disease in only a few instances when fully virulent virus preparations were administered intracutaneously or subcutaneously, it was believed that little danger was involved in the administration of vaccines even though some active virus might be present.

The success in production of active immunity in other virus diseases (foot and mouth disease, louping ill, influenza, psittacosis and herpes) with preparations treated with formaldehyde that contained little or no living virus prompted Brodie⁵ to reapply this method to poliomyelitis. This investigator showed that poliomyelitis virus treated with dilute solution of formaldehyde was noninfectious for monkeys but still produced virus-neutralizing substances if employed while fresh. The stage was thus set for the application of this method to man.

Even while these inoculations were proceeding, three reports by experienced workers in this field appeared denying the effectiveness of immunity produced by either the formaldehyde vaccine (Brodie) or the ricinoleated vaccine. Both Schultz and Gebhardt⁶ and Olitsky and Cox⁷ showed that such "immunized" monkeys were not resistant to intracerebral or intranasal test applications of virus. Gordon⁸ came to a similar conclusion in a study of the response of monkeys to virus adsorbed to alumina gel. However, these facts have been accepted for years. The lack of resistance to such heroic tests as given by intracerebral and intranasal routes does not alone negate the practical value of a vaccine, as antirabic vaccination⁹ and vac-

cination against herpes¹⁰ and louping ill¹¹ likewise fail to produce an immunity against a test dose introduced directly into the nervous system. Cox and Olitsky have produced such an immunity to equine encephalomyelitis¹². Field studies of a vaccine in man seemed to be the only method of determining the worth of vaccination against poliomyelitis.

Paralytic poliomyelitis with high fatality resulted from the use of a vaccine prepared with sodium ricinoleate. Official action by the United States Public Health Service followed the report of Leake¹³. In all, nine cases with five deaths occurred following the use of this vaccine under conditions that clearly incriminated the vaccine, since the disease set in after a characteristic incubation period and paralysis appeared in the same or contralateral extremity in which the vaccine had been given. The unusually high mortality was explained as due to primary involvement of the cervical cord with spread to the medulla. The case against the formaldehyde vaccine (Brodie) is considered by many to be inconclusive and too hastily drawn. Seven cases have been reported¹⁴ at various intervals following the use of this vaccine. All occurred in areas where poliomyelitis was epidemic. In all cases adequate, and in some instances multiple, opportunities for exposure to the natural disease have been traced. The interval elapsing between the last administration of the vaccine and the onset of paralysis was five days, fourteen days, seventeen days, twenty-three days, six weeks, twenty-three weeks and thirty-two weeks. None of these cases can be ascribed to the vaccine with any degree of certainty. The diagnosis is in doubt in two cases and in the latter three the interval between vaccination and onset of the disease was unduly long to incriminate the vaccine. Spasmophilia with low blood calcium and bilateral otitis media initiated disease nine days before weakness was noted in the fourth patient. Even in the one remaining case that was fatal, exposure to the natural disease was traced. Virus was isolated from the spinal cord in this case by Kessel¹⁵ but comparisons to known virus strains have not been completed. However, little is known of the adaptability of monkey virus to man, so that conclusions drawn from such studies can be accepted only with reservations.

Five of the seven cases mentioned occurred in Kern County, Calif., where a controlled study of the vaccine has been carried out by Gifford and Bogen¹⁴. These authors vaccinated 3723 persons during 1935. Contact was traced in more than a thousand cases during that year. Of these, 545 were vaccinated, usually within a

fortnight of exposure. But two cases (0.37 per cent) developed in the vaccinated controls, while six (1.26 per cent) occurred in 477 not so treated. While the incidence of poliomyelitis was little different in the vaccinated population (0.13 per cent) as compared with those remaining unvaccinated (0.14 per cent), opportunity for infection was said to have been definitely greater in the vaccinated group. Among 1,275 school children vaccinated in a case-matching controlled experiment, none developed the disease, while five of a similar number of unvaccinated controls came down with it. In New York and its environs^{16a} 2,850 children have received the vaccine. Two cases developed, one six and another thirty-two weeks after vaccination, under circumstances in which the vaccine could be completely exonerated. Near Philadelphia¹⁶ 500 persons were vaccinated and in North Carolina¹⁷ 458 injections were made. No cases developed in the latter two groups.

While it has been pointed out¹⁸ that poliomyelitis is not a sufficient public health problem to warrant vaccination, as the seasonal incidence of the disease seldom exceeds from 20 to 40 per hundred thousand, the economic disability and psychic trauma produced by residual paralysis lessen such objections to a considerable extent. The possibilities of specific prevention have not been explored to the limit. On account of the isolation of the central nervous system from the rest of the body, even from the blood, future experiments should explore the possibilities of intimate contact between the immunizing preparation and the spinal cord. Evidence points to the poliomyelitis virus as a poor antigen. Greater antigenic mass relative to protein content might increase the effectiveness of vaccines. The past history of formaldehyde vaccine (Brodie) should encourage further attempts to evolve an improved product in the laboratory. If application is again made to man, immunization should be carried out in interepidemic months and in the absence of the epidemic disease, as disregard of these precautions has directed undue suspicion against the vaccine.

Recent immunologic studies have further complicated the problem of vaccination. Aycock and Hudson,¹⁹ who studied blood samples from the immunization experiment in North Carolina,¹⁷ found virus-neutralizing substances to have been produced at the same rate in an unvaccinated control group as among those who received the vaccine. The suspicion that the virus-neutralizing antibodies did not accurately represent the immune state has been raised by the large number of convalescents that do not have these substances. Harmon and his co-workers²⁰ have shown that paral-

ysis can occur with neutralizing substances present in the preparalytic and early paralytic days of the disease in man. If significant at all in active immunity against poliomyelitis, there may be some critical level that determines the immune state. The significance of the neutralizing substances was discussed at length by Harmon and Harkins²¹ in *THE JOURNAL* last week.

While further experimental studies on specific vaccination are awaited with interest, an effective experimental method of blockade of infection at the nasopharyngeal portal of entry has been discovered by three groups of independent workers.²² Tannic acid, trimetaphenol (picric acid) and mercurochrome in suitable dilution sprayed into the nostrils render monkeys refractive to intranasal instillation of virus for many days. Only elaborate field studies can determine whether this method is effective in limiting the spread of poliomyelitis in man.

Current Comment

PROTECTING THE PUBLIC

Control of the profession in the public interest, as clearly shown by Justin Miller,¹ is a function of the state. Expressed in various ways and in differing degrees in successive ages and with respect to the several professions, the power of the state remains, even when dormant, ultimate and unassailable. The regulation of medical practice in such a manner as to safeguard the citizens against the dangers of ignorance and incompetence is therefore one of the most fundamental responsibilities of the state. That the people of the United States acknowledge the vital importance of such regulation is evidenced by the fact that every one of the forty-eight states and the District of Columbia have enacted statutes prohibiting the practice of medicine by unqualified persons. The enforcement of these statutes, however, has been severely hampered, almost nullified, by lack of funds. No state has appropriated funds to provide adequately for the examination of candidates for a medical license. Judgment and skill, which are of the utmost importance in the art of medicine, obviously cannot be appraised by a purely written examination, but the state boards, financially dependent on the fees of applicants, are unable to underwrite the cost of a complete practical examination. Facing this dilemma, the boards, in order to discharge

their obligations to their constituents to the best of their ability, have resorted to the expedient of admitting to the examination only the graduates of approved schools. This procedure is, in effect, the only real safeguard against the licensing of unqualified persons. Since 1907 it has been possible for the states to adopt this policy because the American Medical Association, through the Council on Medical Education, was able to give to the public a trustworthy classification of medical schools. Without such a list, elevation of the standards of medical education and medical practice would have been impossible. The recent survey of medical education has convincingly demonstrated that appraisal of the medical schools of the country is a task far exceeding the resources of any state board. Thus it has come about that the Council, an extralegal body, without power save the power of public opinion, has become the most important factor in the procedure by which the states perform their regulatory function in the field of medicine. To the extent that the states rely on the findings of the Council, the people will be assured that only well trained and competent physicians will be licensed to practice. When examining boards neglect to avail themselves of the information furnished by this association, the character of medical service available in their respective communities must necessarily deteriorate.

EFFECTIVE TEACHING

The Flexner Report¹ of 1910 called public attention to two of the glaring defects of the medical schools of that day. One was the failure to enforce a reasonable standard of preliminary education in the admission of students. Another was the general dependence on didactic methods in the teaching of medicine and the want of hospital and dispensary facilities for personal and practical instruction in the clinical branches. The fixing of entrance requirements brought about a rapid decrease in the number of students and the closing of many of the weakest schools. When, after the war, the number of applicants began steadily to increase, it was usually taken for granted that the number of students that could be effectively taught depended on the size of the preclinical laboratories, and that in the clinical years, if desired, larger classes could be accommodated. Data from the medical schools of the United States and Canada now being analyzed by the Council indicate that the reverse is true. Adequate clinical facilities, under effective control by the school, are enjoyed by comparatively few institutions. Laboratories may be utilized by successive sections, but patients cannot be subjected to repeated examinations. In the preclinical subjects the curriculum can, if necessary, be adjusted to classes of 100 or 150, but the intimate contact of student and patient that is needed for the best type of clinical teaching is rarely obtainable for such large groups. For effective teaching in our medical schools, the factor limiting the size of classes would be in most cases the clinical rather than the preclinical facilities.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

The Poliomyelitis Epidemic—The state health department of Alabama reports that 294 cases of poliomyelitis had been reported in the state from June 1 to August 21, with twenty-four deaths. Up to August 7 the number of cases was 247. Although the spread of the epidemic appears to be declining, Dr. James N. Baker, state health officer, advised against lifting restrictions on gatherings and migrations until no new cases have appeared in a county for twenty-one days. Dr. Baker pointed out that the epidemic has followed the main highways. National Guard encampments and the annual convention of the Alabama Department, American Legion, were postponed because of the epidemic. Newspapers reported August 6 that in Lauderdale County, a northern county which has been one of the principal centers of the disease, a ban on meetings for adults has been removed. Motion picture theaters, churches and other gathering places were closed for several days. The Birmingham *News* reported August 3 that Tennessee had had eighty-one cases with five deaths, Georgia and Mississippi nineteen cases each.

COLORADO

State Medical Meeting in Glenwood Springs—The sixty-sixth annual session of the Colorado State Medical Society will be held at Hotel Colorado, Glenwood Springs, September 9-12, under the presidency of Dr. Walter W. King. Guest speakers will include

Dr. Harold N. Cole. Cleveland. The Syphilis Problem. How Shall We Meet It?

Dr. William W. Bauer. director. Bureau of Health and Public Instruction. American Medical Association. Chicago. Relationships Between the Practicing Physician and the Public Health Worker.

Dr. Henry N. Harkins. Chicago. Surgical Shock from Burns. Freezing and Similar Traumatic Agents.

Clinicopathologic conferences will be held each morning beginning Thursday. At a joint meeting of the society with the Woman's Auxiliary Friday evening Dr. John H. J. Upham, Columbus, Ohio, President-Elect of the American Medical Association, will make an address entitled "These Changing Times in Medicine." Friday morning there will be a presentation of the past presidents of the society in the order of their seniority. Dr. Hubert Work, Englewood, former President of the American Medical Association and Secretary of the Interior under President Coolidge, is the senior living president of the society, having served in 1894-1895. The annual golf tournament will be held on the Hotel Colorado golf course Friday. The annual banquet and president's reception will be held Saturday evening. Dr. Albert C. McClanahan, Delta, will be toastmaster at the banquet, which will be dedicated to Dr. Josiah N. Hall, Denver, in recognition of his fiftieth year of attendance at the annual meetings of the society. He has been a member fifty-two years. Dr. Hall, now 76 years old, has been president of the state society, of the state board of health and of the state board of medical examiners. He served on the Judicial Council of the American Medical Association from 1921 to 1931 and was a member of the House of Delegates at various times from 1903 to 1921. He has been professor of medicine at the University of Colorado School of Medicine for many years. In 1916 he was president of the American Therapeutic Society. Dr. Arthur Jackson Markley, Denver, is the incoming president of the society. Physicians from other states who are members of their county and state societies are invited to attend this meeting.

FLORIDA

Lectures on Tuberculosis—The tuberculosis committee of the Florida Medical Association and the Florida Tuberculosis and Health Association with other cooperating agencies recently conducted an institute in Miami for Negro physicians. Lecturers included Drs. Emile Bryant Woods, Jacksonville, director of the newly created bureau of maternal and child health, state department of health, on gynecologic conditions in persons with tuberculosis. Thomas E. Buckman, Jacksonville, childhood tuberculosis, Mathew Jay Flipse, Miami, director of the institute, symptomatology of pulmonary tuberculosis, George

N MacDonell, Miami, bovine tuberculosis and its relation to tuberculosis in children, Ellsworth C Brunner, physical diagnosis, and James H Putnam, the role of general rest.

ILLINOIS

Expansion of the Elgin State Hospital—A program of expansion is under way at the Elgin State Hospital, Elgin, which ultimately will involve the expenditure of \$14,000,000 in addition to \$3,000,000 which has already been appropriated from PWA funds. Plans have been approved for a diagnostic center, with a maximum of 200 beds, a tuberculosis pavilion, with 100 beds, infirmaries for male and female patients, a cottage for male patients, a two story apartment building to house members of the medical staff and their families, interns and residents, and a two story building for employees, with separate quarters for registered nurses and space for classroom and recreational activities. In the last five years the patient population at Elgin State Hospital has increased from 3,466 to 4,600. During the latter part of 1935, more than 600 patients were transferred to the Manteno State Hospital, Manteno, where a building expansion program has also been under way (THE JOURNAL, February 15, p. 543).

Chicago

Graduate Course on Cancer—The tumor clinic of Michael Reese Hospital is sponsoring a graduate course on tumors during the week September 21-27. Morning sessions will be held at the Palmer House and afternoon sessions at the hospital, except those of Wednesday September 23, which will be at the Veterans' Administration Facility, Hines, Ill. Subjects and speakers are as follows: Monday, symposium on cancer of the breast, with Sir George Lenthal Cheatle, London, Dr. Henri Coutard, Paris, and Dr. Max Cutler as speakers, Tuesday, intra-oral cancer, Dr. Coutard and Dr. Cutler, Thursday, pelvic tumors, Dr. Coutard and Dr. Cutler, Friday, causes of cancer, Sir G. Lenthal Cheatle, and biopsy, Dr. Cutler, Saturday morning, high voltage x-rays, Arthur H. Compton, Ph.D., professor of physics at the University of Chicago, Gioacchino Failla, Ph.D., physicist of Memorial Hospital, New York, and Dr. Coutard. The Wednesday session at Hines Hospital will consist of clinics in which cases of interest from the cancer service of the hospital will be presented. Friday afternoon there will be demonstrations at Michael Reese of radium treatment of cancer of the cervix, insertion of radium needles, construction of radium molds and transillumination of the breast. In the evening there will be a banquet at which Dr. Morris Fishbein, editor of THE JOURNAL, will be the speaker. Sunday will be devoted to informal round table conferences.

INDIANA

Collection of Leonardo da Vinci Drawings—A series of engraved copies of the anatomic drawings in the notebooks of Leonardo da Vinci have been presented to the Indiana University School of Medicine by Dr. George A. Collett, Crawfordsville. The drawings have been in the Royal Library at Windsor since the reign of Charles II, and the prints made in 1795, are the work of Francesco Bartolozzi, a member of the Royal Academy and the historical engraver to King George III. The explanations accompanying the original drawings were written backward with the left hand, as all of da Vinci's notes were written, and must be read with the aid of a mirror. According to the state medical journal, it is supposed that the da Vinci notebooks were taken to England by the Earl of Arundel when he was ambassador at the court of Ferdinand II. They remained unappreciated in the Royal Library until the latter part of the eighteenth century, when they were brought to the attention of William Hunter.

IOWA

Society News.—Dr. Olan R. Hyndman, Iowa City, addressed the Floyd County Medical Society in Charles City, July 28 on intracranial surgery.—William L. Strunk, Sc.D., Decorah, chairman of the board of examiners in the basic sciences, discussed the basic science law and its operation before the Sixth Council District Medical Society and the Poweshiek County Medical Society at Grinnell, June 25.—Speakers at the summer meeting of the Upper Des Moines Medical Society in Arnolds Park, August 6 were Drs. Walter L. Biering, Des Moines on the social security act, Frank J. Heck, Rochester, Minn., practical treatment of the anemias, Edwin W. Miller, Chicago, appendicitis in children, and Edwin B. Winnett, Des Moines, newer developments in the treatment of diabetes, the evening address was delivered by Dr. Frank H. Krusen, Rochester, Minn., on "Medicine Keeps Pace with the Machine Age."

KANSAS

Physician Honored—A certificate of honor for services to his profession and to the Sedgwick County Medical Society was presented, July 22, to Dr. Lloyd P. Warren, a patient in Wichita Hospital. Dr. George E. Milbank, president of the medical society, and Mr. Mac F. Cahal, executive secretary, made the presentation. Dr. Warren has been practicing in Wichita since 1902. He joined the Sedgwick County Medical Society soon after it was organized in 1903, becoming its president in 1914. Dr. Warren has been ill for several months; it was stated. Dr. David W. Basham, past president of the society, is the only other person to have received this tribute from the society, newspapers reported.

LOUISIANA

Society News—At the joint scientific and second quarterly executive meeting of the Orleans Parish Medical Society, July 13, Drs. Arthur Neal Owens discussed "Treatment of Varicose Ulcers of the Lower Extremity" and George W. Robinson, "Local Use of Quinine in Ophthalmology."—A symposium on appendicitis constituted the program of the June meeting of the staff of Mercy Hospital, New Orleans. Speakers were Drs. Philip C. DeVerges, Max M. Green, Edwin L. J. Zander, Lloyd J. Hanches and George H. Hauser.

MARYLAND

Vital Statistics—There were 13,503 births reported in Maryland from January 1 to June 30, as compared with 13,817 during the corresponding period of 1935. A total of 11,564 deaths was recorded, in comparison with 11,253 in the corresponding months of 1935. The greatest increases occurred in the deaths from heart disease and diseases of the kidneys, with 2,718 deaths attributed to the former in 1936 as compared to 2,474 in 1935, and to the latter 1,294 in 1936 against 1,178 in 1935. Communicable diseases showed an increase, with totals of 28,565 in 1936 and 25,123 in 1935. Measles, scarlet fever and whooping cough were responsible for one third of the total sickness reported, while syphilis and gonorrhea, the pneumonias and tuberculosis were charged with another third. There were 350 cases of meningitis in 1936, as compared with 156 during the same period of 1935, 154 cases of diphtheria, six less than last year, nine cases of tularemia, seven of Rocky Mountain spotted fever, fourteen of undulant fever, and six of malaria. With four cases of poliomyelitis, the state recorded one less than the previous year for this period.

MASSACHUSETTS

Centenary Celebration Features Natural Sciences—A symposium on the sciences will be held at Williams College, Williamstown, in October, as a special feature of the centenary celebration of Mark Hopkins' induction as fourth president of the college. Participating in the symposium will be Irving Langmuir, LL.D., of the General Electric Laboratories, Schenectady, N. Y., Herbert Spencer Jennings, Ph.D., Henry Walters, professor of zoology, Johns Hopkins University, Baltimore, and John Clarke Slater, Ph.D., professor of physics, Massachusetts Institute of Technology, Cambridge. William Mansfield Clark, Ph.D., De Lamar professor of physiologic chemistry at Johns Hopkins, who is chairman of the program dealing with the sciences, will preside.

MICHIGAN

Personal—Dr. Robert C. Farrier, Morgantown, W. Va., has been appointed health officer of Delta County, with headquarters at Escanaba.—Dr. Lars W. Switzer, Ludington, has been placed in charge of the new health unit for Mason and Manistee counties; headquarters will be tentatively established at Manistee.

Fellowships at Wayne University—Fellowships in the preclinical basic medical sciences are to be established at Wayne University College of Medicine during the coming year. Fellows will elect a major subject in which they will devote about half their time to teaching and half to research; they will also select a minor subject for graduate study only. They will be registered as graduate students and will be working toward the master's degree. The fellowships are open to students on a competitive basis who have completed the sophomore year of medicine and have the bachelor's degree and to graduates who have the bachelor's and doctor's degrees in medicine. Each fellowship will pay a salary of \$100 a month for ten months and is renewable on recommendation of the head of the department for three years. For further information address Dr. Raymond B. Allen, dean, Wayne University College of Medicine, Detroit.

NEW MEXICO

Tuberculosis Conference—The Rocky Mountain Tuberculosis Conference will be held at the Franciscan Hotel, Albuquerque, September 28-29. Speakers will include

- Dr Raymond J. Friel Salt Lake City Surgical Collapse of the Lung
- Dr James M. Odell The Dallas Ore. Value of Phrenic Nerve Interruption as the Sole Procedure in Pulmonary Tuberculosis
- Dr Felix P. Miller El Paso Modified Technic in Thoracoplasty in Tuberculosis
- Dr Charles F. Stough Colorado Springs Thoracoplasty
- Drs Munford Smith and Howard W. Bosworth Los Angeles When Should Artificial Pneumothorax Treatment Be Discontinued?
- Dr Arthur E. Guedel Beverly Hills Calif. Anesthesia to the Tuberculous
- Dr Harry J. Corper Denver Virulence of Tubercle Bacilli
- Dr John W. Flinn and John S. Flinn B. Sc. Prescott, Ariz. Physiologic Action of Climate and Its Application in the Treatment of Tuberculosis
- Dr John W. Shuman Los Angeles Tuberculosis in the Aged

In addition a sociological section of the conference will discuss problems of case finding and after-care, educating the public about tuberculosis and trends in care of the indigent sick by public agencies. Dr Robert B. Homan Jr., El Paso, Texas, will give an address on "Socialized Medicine as It Affects the Private Sanatoriums." Luncheon sessions will be addressed by Dr J. Arthur Myers, Minneapolis, on "Significance of Tuberculosis in Childhood," and Dr Carl C. Dauer, New Orleans, "Distribution of Tuberculosis Mortality in Western United States."

NEW YORK

Name Changed—The name of the New York State Sanitary Officers' Association has been changed to the New York Health Officers' Association. Dr. Chalmer J. Longstreet, Binghamton, is president. Vice presidents are Drs. Myron M. Metz, Williamsville, Charles G. Lenhart, Spencerport, and James H. Flynn, Troy, the secretary is Dr. Guy H. Turrell, Smithtown Branch.

New York City

Training for the Specialties at Post-Graduate School—New York Post-Graduate Medical School announces that henceforth training provided as a preparation for practice of a specialty will be restricted entirely to residencies in the hospital, except the training offered in the departments of dermatology and radiology. Courses for the general practitioner have been shortened to a maximum of three months.

Sentenced for Fraudulent Insurance Claim—Dr. Abraham Benjamin was sentenced July 27 in the court of general sessions to serve from fifteen months to two and a half years in Sing Sing for a fraudulent accident claim. He is said to have conspired with a man who posed as a lawyer to defraud insurance companies. The probation officer reported that Dr. Benjamin had furnished affidavits for fraudulent claims for fourteen years.

Increase in Acute Alcoholism—Admissions to Bellevue for alcoholism during the first six months of 1936 were at the rate of 12,378 for the year, the department of hospitals recently reported. This is a large increase compared with 9,139 cases in 1935 and 7,649 in 1934. The most serious situation in connection with alcoholic patients arises from the number who fall and sustain a head injury, the report said. A special operating room will be opened this fall in the psychiatric pavilion for surgical treatment of head injuries.

New Corporation to Finance Health Department Research—A non profit making corporation known as Health Research Inc. was recently formed by the New York City Department of Health to accept and administer funds offered for financing research in the city's laboratories. For many years private contributions have been made to finance research under the direction of Dr. William H. Park as Biggs professor of preventive medicine and director of bacteriologic laboratories at New York University College of Medicine and administered by the college. Dr. Currier McEwen, assistant professor of medicine, assistant dean and secretary at New York University College of Medicine was elected president of the new unit, Dr. Park vice president, and Dr. Wade W. Oliver, professor of bacteriology, Long Island College of Medicine, Brooklyn secretary. The department plans to open a convalescent serum center under the new arrangement.

Brooklyn Cancer Institute in New Quarters—The new Brooklyn Cancer Institute will be opened at Kings County Hospital about September 15 as an independent clinical unit of the division of cancer of the city department of hospitals, with Dr. William E. Howes as administrative clinical director.

There will be three services surgical, with Dr. John E. Jennings as director, medical, with Dr. Henry M. Moses as director, and radiotherapy, with Dr. Howes as director. The three directors are to be responsible as a committee for clinical policy in general and for the treatment and care of patients individually. For general administrative purposes the institute is under the supervision of the medical superintendent of Kings County Hospital. A visiting staff of thirty-one physicians has been appointed. It is planned that beds are to be used as far as possible for cases of doubtful classification and for recognized tumor cases requiring short hospitalization so that the patients who are still reclaimable may find facilities for care. The institute was formerly at Cumberland Hospital.

OHIO

Society News—At a meeting of the Seventh Council District of the Ohio State Medical Association in Cadiz, June 24, speakers were Drs. Clyde L. Cummer, Cleveland, on "The Present-Day Diagnosis and Treatment of Syphilis" and Clifton F. McClintic, Moundsville, W. Va., "The Personality of the Criminal"—Dr. Roy Glenn Spurling, Louisville, Ky., addressed the Hempstead Academy of Medicine in Portsmouth July 13, on injuries to the head.

Personal—Dr. Archie J. Martin, Wheeling, W. Va., has been appointed health officer of Belmont County to succeed Dr. Frank R. Dew—Dr. William R. Coleman, Bremen, has been made health officer of Fairfield County—Dr. Paul M. Moore Jr., formerly assistant professor of otolaryngology, State University of Iowa College of Medicine, Iowa City, has been appointed to the staff of the Cleveland Clinic to fill the vacancy caused by the death of Dr. William V. Mullin—Dr. John A. Carter, New Paris, has been appointed health commissioner of Clermont County.

OKLAHOMA

Personal—Dr. Leroy Long, Oklahoma City, former dean and professor of surgery, University of Oklahoma School of Medicine, has been chosen for the state hall of fame by the Oklahoma Memorial Association. He will be a guest of honor at the annual statehood day dinner November 16.

Society News—The Tulsa County Medical Society recently voted that its members would not practice in hospitals that charge a fee that includes medical service, either by interns or by members of their staffs—The Oklahoma Tuberculosis and Health Association will conduct an institute in Tulsa September 24, speakers will include Drs. Lewis J. Moorman, Oklahoma City, on "Procedure in Finding Source of Contact in Children Showing Reaction to the Tuberculin Test" and Robert M. Shepard, Tulsa, president of the association, "Manifestations of Early Tuberculosis and X-Ray Interpretations"—Dr. Andronicus J. Wells, Calera, was elected president of the Southeastern Oklahoma Medical Association in July at a meeting in Poteau.

RHODE ISLAND

Publicity Committee Appointed—At the recent annual meeting of the Rhode Island Medical Society a publicity committee was appointed with Dr. James W. Leech, Providence, as chairman and the following members: Drs. Russell S. Bray and Peter P. Chase, Providence, Charles Bradley, East Providence, Guyon G. Dupre, Woonsocket, Stanley Sprague, Pawtucket, Alfred M. Tartaglino, Newport, George L. Young, East Greenwich, and John W. Helfrich, Westerly. Functions of the committee as outlined are threefold: to abstract scientific papers for the lay press, to serve as a mouthpiece for the medical profession when the press desires an expression of opinion on some question of medical policy, and to institute propaganda for the enactment of beneficial and the defeat of harmful legislation.

SOUTH CAROLINA

New Health District Officers—Dr. Clair A. Henderson, Williamstown, has been made health officer of the district composed of Dillon and Marion counties, with headquarters at Dillon. Dr. Goodman Bare, Starr, has been placed in charge of the district including Edgefield, McCormick and Saluda counties, and Dr. George H. Zerbst, Charleston, of the district consisting of Sumter, Clarendon and Lee counties.

Society News—The Eastern Carolina Medical Assembly, comprising the counties of Marion, Dillon and Horry, met June 23 at Myrtle Beach. Speakers were Drs. Julian P.

Price, Florence, on "Pernicious Malaria in Children", George H. Bunch, Columbia, "Mortality in Acute Appendicitis", Alfred R. Shands Jr., Durham, N. C., "Fractures of the Lower End of the Humerus", Walter R. Mead, Florence, "Cerebral Thrombosis," and Robert E. Seibels, Columbia, "Maternal Mortality in South Carolina." Dr. James A. Hayne, Columbia, state health officer, participated in the discussions.

TENNESSEE

Society News—Dr. James B. Neil, Knoxville, addressed the Campbell County Medical Society, La Follette, July 30, on transurethral prostatic resection—At a meeting of the medical society of Cumberland, Jackson, Overton, Putnam and White counties Drs. Andrew F. Richards, Sparta, and Harlan H. Taylor, Cookeville, spoke on "Ether Anesthesia" and "Acute Surgical Emergencies of the Abdomen" respectively—Dr. Cecil E. Newell, Chattanooga, will address the first fall meeting of the Hamilton County Medical Society, September 3, on "Surgical Treatment of Goiter"—Speakers before the Five-County Medical Society (Hardin, Lawrence, Lewis, Perry and Wayne counties) in Waynesboro July 28 were Drs. Leo C. Harris Jr. and Harrison H. Shoulders, Nashville, on "Congenital Cystic Disease of the Lungs" and "Diagnosis of Acute Abdominal Conditions" respectively—Dr. Charles C. Stockard, Lawrenceburg, reported a case of agranulocytosis—Dr. William Britt Burns, Memphis, addressed the Rutherford County and Stone River Academy of Medicine, July 8, on "Cerebral Hemangioma"—Dr. Edward William Alton Ochsner, New Orleans, addressed the Chattanooga and Hamilton County Medical Society, July 15, on "Treatment of Peptic Ulcer Based on Physiologic Principles."

TEXAS

Sentenced for Using Mails to Defraud—J. Howard Christian, a pharmacist of Fort Worth, was recently sentenced to two years in the federal penitentiary at Leavenworth, Kan., following conviction on a charge of using the mails to defraud. At the same time he received a suspended sentence of five years on two other counts of the indictment which was brought after he had attempted to obtain the annual registration permit of a deceased physician. In addition to the federal prosecution Christian was prosecuted by the state for forgery and sentenced to two years in the Texas State Penitentiary for having forged the physician's name to his application for the registration. Christian was first arrested in January 1935 by the special agent of the Texas State Board of Medical Examiners. After his conviction in the state courts he appealed the case, but his conviction was affirmed and a rehearing was denied.

VIRGINIA

New Health Officers—Dr. Robert D. Hollowell, Charlottesville, who recently received the certificate in public health from Johns Hopkins University School of Hygiene and Public Health, Baltimore, has been appointed director of the health district including Albemarle County, Charlottesville and the University of Virginia. He succeeds Dr. Charles Howe Eller, who recently became assistant director of the state bureau of rural health. Dr. Hugh B. Magill Jr., Norfolk, has been made director of the Northampton County Health department to succeed Dr. Albert B. McCreary, Eastville, who resigned to join the Florida State Department of Health. Halifax and Pittsylvania counties heretofore in a joint health district now have separate departments with Dr. Daniel C. Steelsmith, South Boston, in charge in Halifax and Dr. William H. Walcott, Chatham, in Pittsylvania. Dr. George C. Waters, Williamsburg, has resigned as director of the Peninsula health district which includes Warwick, Elizabeth City, James City and York counties.

WASHINGTON

Society News—Dr. Warren B. Penney, Tacoma, was elected president of the Washington State Tuberculosis Association at the annual meeting at Longview, June 18-20—Speakers at a meeting of the Yakima County Medical Society, Yakima, June 8, were Drs. Louis P. Gambee, Portland, on "Some Phases of the Intestinal Obstruction Problem," John R. Montague, Portland, "Nonmyxedematous Hypothyroidism," and Walter Raymond Jones, Seattle, "Venereal Disease Patient's Assets"—Dr. Raymond H. Somers, Seattle, was elected president of the Washington State Society for Mental Hygiene at its annual meeting in Tacoma, June 4.

WEST VIRGINIA

Society News—Drs. Chester D. Christie and John W. Holloway, Cleveland, addressed a joint meeting of the Monongalia, Marion and Harrison county medical societies recently in Morgantown, on "Thyrotoxicosis in the Aged" and "Duodenal Ileus" respectively—Dr. Arthur A. Shawkey, Charleston, addressed the Boone County Medical Society, Madison, July 15, when the society was installed as an official component of the West Virginia State Medical Association. Dr. William V. Wilkerson, Highcoal, is president, and Dr. Robert L. Hunter, Whitesville, secretary—Dr. Oscar B. Biern, Huntington, addressed the Cabell County Medical Society, Huntington, July 9, on "Graphic Registration of the Heart Action."—At a meeting of the Kanawha Medical Society, Charleston, recently Dr. William C. Stewart, Charleston, spoke on "Rheumatic Fever and Rheumatic Heart Disease in West Virginia."

WISCONSIN

State Medical Meeting at Madison—The ninety-fifth annual meeting of the State Medical Society of Wisconsin will be held in Madison, September 9-11, at the Memorial Union. The first day will be devoted to a joint meeting with the cancer institute sponsored by the University of Wisconsin, announced in *THE JOURNAL* August 8, page 438. The remaining two days will be occupied with general and section meetings, round table luncheons and symposiums. Guest speakers at general sessions will include:

Dr. John D. Camp, Rochester, Minn., "Ray Diagnosis of Tumors of the Brain and Spinal Cord"
Dr. Richard W. Telford, Baltimore, "Pathologic Significance of Bleeding After the Menopause"
Dr. James E. M. Thomson, Lincoln, Neb., "Removal of Internal Fixation After the Reduction of Certain Fractures by Use of a Beaded Wire"
Dr. James A. Johnson, Minneapolis, "Treatment of Carcinoma of the Rectum in the Inoperable Case by Electrocoagulation"
Dr. Arthur F. Bratrud, Minneapolis, "Injection Treatment of Hernia"
Dr. Meredith F. Campbell, New York, "Pyuria in Children"
Dr. Claude F. Dixon, Rochester, Minn., "Practical Considerations in Treatment of Colonic Carcinoma"

Guests who will address section meetings and participate in symposiums include:

Drs. Kaare K. Nygaard and Mandred W. Comfort, Rochester, Minn., "Determination of Potential Hemorrhage in Cases of Jaundice by the Photo-Electric Method"
Dr. Avery D. Prangen, Rochester, Minn., "Clinical Problems in Refraction"
Dr. Francis L. Lederer, Chicago, "Problems in Diagnosis and Treatment of Malignancies of the Nasal Accessory Sinuses"
Dr. Joseph L. Miller, Chicago, "The Problem of the Ameba Histolytica Carrier"
Dr. John H. Skavlem, Cincinnati, "Basic Points in Roentgen Ray Studies of Lung Anatomy and Pathology"
Dr. Nathan A. Womack, St. Louis, "Carcinoma of the Bronchus and Its Surgical Treatment"
Dr. John Alexander, Ann Arbor, "Bronchiectasis"
Dr. Jerome R. Head, Chicago, "Acute and Chronic Empyema"
Dr. M. Herbert Barker, Chicago, "Cyanate Therapy of Hypertension"

The annual dinner will be held at the Hotel Loraine, Thursday evening, September 10, with Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, as the speaker. His subject will be "The Hospital and the Doctor." Dr. Fishbein will also address the Women's Auxiliary Thursday morning.

HAWAII

Hawaii's Record Low Death Rate—The lowest mortality rate on record for the Territory of Hawaii was achieved in the fiscal year ended June 1935 with a rate of 8.42 per thousand population exclusive of nonresidents, according to the annual report of the board of health recently issued. This figure compares with a rate of 9.69 in 1934. There were 3,236 deaths, a decrease of 443 or 12 per cent, under 1934. The lowest infant mortality rate was also recorded in 1935. There were 957 deaths or a rate of 64.53 per thousand live births. There were 9,252 births recorded. Forty-four mothers died from puerperal causes during the year. The maternal death rate was 4.64 per thousand live births and stillbirths. There were 3,578 cases of communicable diseases reported as compared with 8,870 in 1934. The most notable reduction was for diphtheria of which there were fifty-three cases with no deaths. There were 2,995 cases of tuberculosis with 307 deaths, giving a new low rate of 80.4 per hundred thousand of population. Earlier rates were 99.7 in 1933 and 89.19 in 1934. Two cases of plague were found in human beings and ten in rodents. The sum of \$705,587.88 was expended during the year for health activities. Additional expenditures included \$1,218.63 for plague activities, \$1,987.72 for diphtheria immunization and \$571.01 for medical inspection of school children.

PHILIPPINE ISLANDS

Society News—The Leyte Medical Association was organized with sixteen members recently. Dr. Anotolio Dasmarrinas was elected president and Dr. Federico Campos, secretary. Dr. Pedro T. Lantim, Manila, addressed the Tayabas Medical Society, Lucena, May 3, on typhoid fever. Dr. Fernando Calderon addressed the Manila Medical Society recently on treatment of retroversion of the uterus. Drs. Antonio G. Sison and Jose G. Cruz presented a case of hyperparathyroidism.

GENERAL

Applications for Certificates of Special Board.—The American Board of Psychiatry and Neurology announces that applications for certificates to be granted at its next meeting, December 29-30, must be sent before October 30 to the secretary, Dr. Walter Freeman, 1028 Connecticut Avenue, Northwest, Washington, D. C.

Industrial Accident Boards and Commissions.—The International Association of Industrial Accident Boards and Commissions will hold its twenty-third annual convention in Topeka, Kan., September 21-24, under the presidency of G. Clay Baker, commissioner of workmen's compensation in Kansas. Tuesday, September 22, will be devoted to a consideration of medical problems associated with workmen's compensation including injection method of treatment of hernia, effect of trauma in lighting up tuberculosis, measurement of schedule injuries under the various laws, and rating of eye disabilities. In addition, the association for the first time will conduct a separate medical section meeting Wednesday for physicians, dealing with technical medical subjects in relation to workmen's compensation. Dr. John F. Hassig, Kansas City, Kan., is chairman of the medical committee.

Prevalence of Smallpox.—A recent analysis of the geographic distribution of smallpox in the United States and Canada by the Metropolitan Life Insurance Company revealed that eight of the most sparsely populated states accounted for 5,054 of the 8,021 cases in the United States. The combined smallpox prevalence rate of these eight states (Washington, Idaho, Montana, Wyoming, Colorado, South Dakota, Nebraska, and Kansas) was 64 cases per hundred thousand of population. The other forty states with an aggregate population of nearly 120,000,000 reported 2,967 cases giving a case rate of only 25 per hundred thousand. There was no smallpox in seven states (Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, Pennsylvania, and Rhode Island) while in ten others less than one case was reported for every 100,000 inhabitants. None of the states east of the Mississippi except Wisconsin experienced sickness rates in excess of three cases per hundred thousand of population during 1935.

Sixteenth Century Indian Herbal to Be Published.—The Smithsonian Institution, Washington, D. C., has arranged to publish what is said to be the first medical book produced in the New World. The *Badianus Manuscript*, written in Aztec and translated into Latin. The original title was 'A Book of Indian Medical Herbs composed by a certain Indian physician of the College of Santa Cruz who is not theoretically learned but is taught only by experience. In the year of our Lord Saviour 1552.' Martin de la Cruz was the author and Badianus the translator both students at the College of Santa Cruz, the first college in the New World, established by the Spaniards for the Indians. Martin de la Cruz wrote in detail of diseases and remedies for them and produced brilliantly colored illustrations of the plants used in Aztec medicine, which have deteriorated little, according to an account in the *New York Times*. The manuscript found its way to Europe and eventually to the Vatican Library, where an investigator for the Smithsonian Institution found it about five years ago during a search for early Latin American texts. The translation and annotation of the Latin and Aztec text was made by Emily Walcott Emmart, Ph.D., Johns Hopkins University, Baltimore.

Prevention of Blindness.—The National Society for the Prevention of Blindness has issued its annual report for 1935. During the year the society cooperated in three summer session courses for the training of sight saving class teachers. Buffalo, Cleveland, and Teachers College, Columbia University, New York. The number of sight saving classes increased from 458 in 1934 to 476 in 1935 and in New York alone five new classes were established in the fall. In its continued drive for the use of safety glass in automobiles the society reports that twenty-three states and the District of Columbia have enacted laws making this mandatory. The society and the American Museum of Safety collaborated in a study of accidents resulting from fireworks with the financial assistance of the American Pyrotechnic Industries. It was disclosed that 7,738 per-

sons were injured and at least thirty persons were killed celebrating July 4, 1935. Of the 3,000 cases in which it was possible to obtain first hand information by means of a questionnaire or by personal visits, 214 had eye injuries, 104 of which were serious. Preliminary figures at the time the report was drawn up showed that ophthalmia neonatorum had decreased to 7.4 in 1935 from 8.2 in 1934. The society expended about \$133,879 during the year.

FOREIGN

International Congress of Urology.—The sixth International Congress for Urology will be held at the Kunstlerhaus, Vienna, September 9-12. The subjects for discussion are treatment of carcinoma of the prostate, suppuration of the renal parenchyma, and the physiology and pathology of renal excretion. Among American speakers listed on the program are Drs. Edward L. Keyes, Joseph F. McCarthy, and Henry G. Bugbee, New York; William F. Braasch, Rochester, Minn.; Hugh H. Young, Baltimore; Louis E. Schmidt, Chicago; George G. Smith, Boston; and Hugh Cabot, Rochester, Minn. Dr. Keyes is president of the International Society for Urology and Dr. Young a vice president of the congress.

International Society of Microbiologists.—At the second International Congress of Microbiology in London, July 25-August 1, speakers included the following Americans:

Dr. Francis Peyton Rous, New York, Evidence Concerning the Agency of Virus Diseases in the Etiology of New Growths
Edwin O. Jordan, Ph.D., Chicago, Bacteria Causing Acute Inflammation of the Alimentary Tract and Their Mechanism of Action
Dr. Hans Zinsser, Boston, Typhus Fever and the Rickettsias
Dr. Ernest E. Tyzzer, Boston, Coccidia in Relation to Domesticated Animals
Dr. Eugene L. Opie, New York, Significance of Allergy
Michael Heidelberger, Ph.D., New York, Structure of Natural and Synthetic Antigens
Dr. William H. Park, New York, Control of Diphtheria and Whooping Cough by Means of Specific Immunizing Reagents
Dr. Jesse G. M. Bullowa, New York, Serum Treatment of Pneumonia
Dr. Augustus B. Wadsworth, Albany, N. Y., The Relative Value of Antitoxic and Antibacterial Immunity in the Prophylaxis and Serum Treatment in Human and Animal Diseases in Which the Invasion by the Causative Bacterium May Occur in a Focal or Generalized Form.

A demonstration of procedure and apparatus for preservation in 'lyophile' form of serum was presented by Earl W. Florsdorf, Ph.D., and Dr. Stuart Mudd, Philadelphia.

Deaths in Other Countries

Sir Alfred Keogh, who was director general of the British Army Medical Corps during the World War, died in London July 30, aged 79.—Dr. Luigi Devoto, professor of pathology, University of Pavia and an authority on occupational diseases, died July 20 in Milan, aged 72.—Prof. Friedrich Breinl of the University of Prague, Czechoslovakia, died July 29 of Rocky Mountain spotted fever, aged 48.

Government Services

Examinations for Medical Officers

The U. S. Civil Service Commission announces open competitive examinations for the positions of medical officer at \$3,800 a year, associate medical officer at \$3,200 and assistant medical officer at \$2,600 a year, to fill vacancies in various branches of government service. To become eligible, applicants must qualify in one of the following branches of medicine and must state the branch or branches desired: cardiology, cancer diagnosis and treatment, eye, ear, nose and throat (singly or combined), urology, internal medicine and diagnosis, neuropsychiatry, pathology and bacteriology, roentgenology, surgery, general, chest and orthopedic, tuberculosis, venereal disease (clinical and public health aspects), industrial medicine and general practice. Applicants will not be required to report for examination at any place but will be rated on education and experience. Candidates for the position of medical officer must not have passed their forty-fifth birthday and for the lower grades, their thirty-fifth birthday. Further details and application forms may be obtained from the secretary, Board of U. S. Civil Service Examiners at any first class postoffice, from the commission at Washington, D. C., or from its district offices in the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z., and San Juan, Puerto Rico. Applications must be filed before September 8.

The Nutrition of the People

In the house of commons a debate took place on the nutrition of the people—a question which unfortunately has become the subject of political propaganda. Mr. Johnston, a labor member, moved a resolution expressing concern at "widespread malnutrition." He quoted an estimate of \$1,000,000,000 as the cost of national ill health and said that there was an accumulating mass of chronic underfeeding and underdevelopment among the poor. The adjutant general in his report for 1934 stated that "over 52 per cent of the men who went to the recruiting offices did not come up to the physical standard laid down. In the big industrial areas of the North the percentage of rejections rose to 68." The chief medical officer of health for the department of education in this report for 1934 said that twelve per thousand of school children were malnourished and fourteen per thousand undernourished. "It had been proved by Sir John Boyd Orr that 4,500,000 people in this country were trying to live below the minimum standard of the British Medical Association." We had organized limitation of production and restriction of markets. We drank one third of the quantity of milk per head that the Swede or Norwegian drank and one half of what the Yankee drank.

Sir Kingsley Wood, minister of health, said in reply that in the matter of nutrition this country had taken the initiative not only in investigation but in action. The word "malnutrition," on which Mr. Johnston hung his indictment, was much abused. He had not explained that the term meant much more than want of food—one more example of how a matter which was largely scientific and economic could be twisted for other purposes. He had quoted from Dr. M'Gongle's book 'Poverty and Public Health' that the death rate of the 30 shilling family was double that of the 75 shilling. But the minister could quote from M'Gongle too, who pointed out the loose and confused manner in which the word malnutrition had been used and said that in the sense of implying an insufficient intake of food it was rare but if it was used to signify a deviation from bodily growth or function attributable to qualitative defects of diet a high percentage of our population must at one time or other have been the victims of malnutrition. Mr. Johnston had also quoted Sir John Orr, who was a distinguished member of the minister's advisory committee. When his book was published one paper went so far as to use the headline "Sir John Orr's Indictment: Fifty per Cent of the People Starving." Those who quoted him should remember his final conclusion. There is need for further investigation and further discussion of the whole question in all its complicated relationships. An equal authority and another member of the minister's committee Professor Cathcart said that malnutrition was due not so much to poverty as to ignorance and other causes of the same kind. Another authority, Sir Robert Hutchison, said that diseases due to overnutrition were increasing while those due to undernutrition were diminishing. If the allegations made were accurate and there was widespread malnutrition, the health of the population would be rapidly declining. But viewed over any period that enabled just comparisons to be made our national health was improving not merely steadily but remarkably. Again, if the allegations were true our low death rates became difficult to explain. In the last twenty years we had added seven years to the expectation of life and reduced the infant mortality from 100 to 57 per thousand births. Another test was the incidence of tuberculosis and rickets. The death rate from tuberculosis was now less than a quarter of the rate fifty

years ago. The number of deaths from rickets was only half the number five years ago and there had been a progressive diminution in the number of patients with active disease. Another test was the condition of the children. Recent medical inspections of over a million and a half school children showed that the condition of 146 per cent was excellent, 74 normal, 106 slightly subnormal, and only 07 bad. Medical reports from the post office showed that the boys of 16 applying for employment were on the average 16 pounds heavier and 1½ inches taller than those of twenty-five years ago. Girls of the same age were 10 pounds heavier and 1 inch taller than those of the corresponding class twenty-five years ago. The rejection of recruits for the army was used to build up a case. The standards of recruitment were high and were based on the principle that men must be fit to serve all over the world in tropical as well as temperate climates. The rejections—about 35 per cent—did not reflect on the general health but were due to such causes as disease of the middle ear, defective teeth and defects of the lower limbs. Even in the areas depressed by unemployment, only signs of strain due to this cause were found and steady improvement in this direction was taking place. Malnutrition must be fought and increasing attention must be paid to the nutrition of the people. The government had adopted a policy to increase the consumption of milk. About 2,250,000 school children were receiving a daily ration of a third of a pint of milk for 1 cent and free milk was given to 300,000. Nearly all the maternity and child welfare authorities provided milk free or at cheap rates. The government was willing to support any practicable proposals for extending the scheme. The resolution was rejected by 359 votes against 139.

Anglo-French Surgical Meeting

By invitation of the president and council of the Royal College of Surgeons, members of the Académie de chirurgie attended a discussion at the college. They also visited St. Bartholomew's Hospital and the London Hospital, where they witnessed the operations.

Professor Hey Groves introduced the subject of the operative treatment of fracture of the neck of the femur. He confined his remarks to subcapital and transcervical fractures, which were almost entirely intracapsular and difficult to treat because of the poor blood supply of the head of the bone and the tendency to absorption of the neck. Accurate apposition and firm fixation were essential. For many years Whitman's method of plaster fixation held first place, but it was long and tedious and a strain on old patients and yielded only 50 per cent of successes. During the last six years the situation had been dominated by the Smith-Petersen three-flanged nail. The original operation entailed an incision of considerable size. Professor Hey Groves set himself the problem of inseting the nail without such open operation. He devised an instrument to guide the drill into the axis of the head and neck, which he exhibited. It had three vertical points, two of which were thrust through the skin and the third, which took the drill guide, lay outside the thigh. It was necessary to ascertain two points: the middle of the head of the femur and the point at the base of the neck where the axes of the neck and the shaft crossed each other. These points were obtained with the help of the x-rays and were marked on the skin. Only two tenotomy wounds were necessary for the introduction of the instrument. The drill having been thrust into the thigh and through the neck into the head the instrument was removed leaving the drill in position. A small incision was made with the drill as its center and the modified Smith-Petersen nail hammered in. The procedure was simple and did not impose too great strain on the old and feeble.

Mr. Watson-Jones showed a motion picture of his drill guide method. He had operated on sixty-four patients with a mortality of 6 per cent—a figure lower than could be secured by

other methods Bony consolidation was secured in 91 per cent His technic consisted in inserting a stout drill guide under visual direction, which ensured accurate insertion of the nail.

Mr Gwynne-Williams said that he had treated thirty-one cases of unimpacted fracture by the Smith-Petersen open operation The average age of the patients was 65 He had six deaths—two from pulmonary embolism, one a year after operation from infection with *Bacillus Welchii*, one from septicemia, one from erysipelas and one from pyelonephritis The operation involved no great loss of blood and no shock

Mr Edmund Lloyd advocated the lateral approach He showed an instrument of precision which enabled the nail to be inserted through a small incision over the great trochanter, without the use of wires and without exposure of the fracture His method required a developing room adjacent to the operating room or a portable dark room in the operating room and a radiographic staff able to take good lateral pictures

Recent Work on Surgical Shock

Dr John Beattie conservator of the museum of the Royal College of Surgeons, described recent work at the college laboratories on surgical shock Experimental animals showed three stages. The first fall in blood pressure after trauma was due to loss of fluid The period of recovery might last thirty minutes and then a gradual fall, terminating in death, took place. The work done in the laboratories pointed to the conclusion that the loss of fluid during the first phase was not the cause of death, which was due to something happening in the second stage, probably associated with impulses passing along the sympathetic nerve. Perhaps these impulses brought about some change in the central nervous system that was irreversible, and in consequence the blood pressure kept on falling until it became so low that death was inevitable An animal shocked by trauma of the hind limb might die in two and one-half hours But if the spinal cord was blocked by procaine hydrochloride the blood pressure was maintained and the animal was prevented from passing into a condition of shock Cross circulation experiments confirmed the conclusion that the lethal factor in shock was abnormal nerve impulses

Influence of Recent Social Laws on Leisure

Two recent laws are now in effect in France. One of these fixes the maximum number of working hours per week at forty, and according to the other law every employer is obliged to grant a paid vacation of two weeks annually to all employees who have been in his service for more than a year Several interesting developments have followed the enactment of these laws First, a government department has been created called the department of leisure, which will not only advise workers how to spend the hours in which they are not employed but also aid them as to where to spend their two weeks paid vacation period as cheaply and pleasantly as possible. The latter includes special excursion rates, in both summer and winter, to all parts of France.

A second development may appear strange to those who remember how the prohibition law in the United States was regarded as something that would never be needed in France At the June 9 meeting of the Academie de medecine, the leading medical organization in France, Dr Sieur stated that, as one desired that the forty hours a week law should fulfil the hopes of those who planned it, the following clauses ought to be inserted 1 To limit the number of saloons (bistrot) and to control carefully the quality and quantity of alcoholic drinks dispensed by the reduced number of saloons 2 That all cities possessing a large number of workers should make every effort

to place at their disposition large areas of land, in which gardens could be developed by those obliged to work in congested industrial centers This second suggestion will especially impress those who have visited France and observed the paucity of recreation parks in densely populated portions of Paris and other large cities

Following the introduction of Dr Sieur's resolution, a special committee was appointed to investigate these two questions This committee submitted its report at the July 7 meeting, stating that in 1926 the Academy of Medicine had called attention to the marked increase in the consumption of alcoholic beverages in the postwar period Unfortunately this warning was not listened to, and as a result the question of alcoholism has become a very serious one One of the principal reasons why alcoholism has increased is the huge and rapidly increasing number of saloons Whereas in many foreign countries strict control exists, the government pays no attention at all to the question in France. In most countries the tax on alcohol is very high and its sale is limited to specially controlled agents, but in France such a tax is far below what it ought to be Under the loose supervision of saloons that exists in France, the medical profession is observing an increasing number of cases of insanity, cruelty to children and street accidents The Academy agrees with the government that every possible means should be employed to ameliorate the condition of the working classes and hence suggests that the government should apply the following 1 Limit the number of saloons and control the preparation of drinks sold in them 2 Organize recreation centers for adults, in which only nonalcoholic drinks are sold 3 Increase the number of playgrounds where the greatest possible attention shall be paid to physical development of young people 4 Establish city gardens where the working people can raise some of their own vegetables, also construct hygienic dwellings to replace the many hovels of the large cities

Treatment of Neuralgias by Radiotherapy

Radiotherapy occupies an important place at present in the treatment of neuralgia This is especially true of pain due to spinal nerve root inflammation due to rheumatism Minute doses are employed, much smaller than those employed in the treatment of cancer Usually, at a single sitting, from 75 to 250 roentgens is given over the nerve roots or the involved plexus, the total dosage being from 1,000 to 2,500 roentgens Some radiologists employ an even higher dose At the May 8 meeting of the Societe medicale des hopitaux, Coste and his associates called attention to the fact that this method is often followed by an exacerbation of the pain Some radiologists are inclined to disregard such a result, whereas others, like the authors, considered such exacerbations a marked objection Usually the increase of pain diminishes rapidly and then its relief follows Coste and his associates, however, have observed that in some cases the exacerbation of pain does not cease so suddenly but continues for some length of time, so that the patient suffers intensely Hence prudence demands some modification of the dosage, lest this remarkable method fall into disrepute. The experience of the authors has convinced them that the relief of pain in these neuralgias can be obtained even though minute doses frequently repeated, and with short sittings, are used They observed, even after ordinary radiography of the chest, spine and abdomen the marked amelioration of pain in cases of neuralgia of rheumatismal origin Since then they have irradiated small fields which correspond to the nerve roots involved, using 180 kilowatts tension, 0.5 mm of copper and 2 mm of aluminum filtration, an intensity of 3 milliamperes and a distance of from 30 to 40 cm Ninety-seven patients have been thus treated, without any other (internal) medication, and the results have been highly satisfactory, as shown by a tabula-

tion of their cases. This method of minute doses does not exclude the use of higher doses, which, if added, are not followed by any such exacerbation of pain as is observed when doses of medium or high intensity are employed from the beginning of the irradiation. The loss of time in using the smaller doses at first is insignificant as compared to the frequency of increased pain after initial large doses. Radiotherapy alone will not relieve all cases, hence it should be associated with anesthesia (by nerve blocking) of the nerve trunks by the paravertebral or epidural route, injection of irritants at some distance from the nerve, and the treatment of the underlying cause of the neuralgia. Coste and his associates agree with those who believe that irradiation is followed by a local alkalosis of the tissues around the inflamed nerve trunks.

In the discussion, Haguenau stated that he has always used a relatively high dosage in irradiation but that relief had been observed to follow smaller doses even at the beginning of treatment. He agreed with the authors as to the efficacy of minute doses. In the majority of cases, Haguenau has found that relief is obtained only with doses of medium intensity, it being necessary to give as much as 2,000 or 3,000 roentgens before the pain ceases. He objects to the employment of irradiation for neuralgias simultaneously with physical therapy or local injections, as Coste advocated, because one would never be able to say which of the various methods had been efficacious.

The Recent Decline in Tuberculosis Mortality

In the June 15 *Siccle médical*, Marcel Moine, statistician of the National Committee to Fight Tuberculosis, cites figures showing that there has been a marked decrease in the number of deaths from this disease. The city of Paris and the adjacent region was chosen to demonstrate this decrease, because the statistics are more accurate here than elsewhere in France, only 2 per cent of the total number of deaths being reported as "unknown." From 1895 to 1908 the mortality from tuberculosis was as high in Paris as in the surrounding territory. From 1908 to 1918 the curve for Paris showed a decline, while that for the suburbs showed a rise until 1918. This is explained by the intensive migration of city dwellers to the adjacent country from 1908 to 1918. From 1920 to 1926 the mortality in both city and suburbs was about equal. Then a decline followed for both, which has continued to such an extent that by 1940 the author believes that the mortality for Paris (195 per hundred thousand inhabitants) and for the suburban region (165 per hundred thousand) will be about equal to that of the remainder of France. These figures show that up to 1914 the mortality from tuberculosis in the Parisian suburbs was constant and the same was approximately true for the city itself up to 1908, the average being 450 per hundred thousand. In 1935 this figure dropped to less than 200 per hundred thousand, a decrease of 55 per cent. This means on the basis of the present population of the city a saving of 9,400 lives a year, of whom 6,200 are between the ages of 20 and 50. Further curves show that the improvement is not only quantitative but also qualitative. Adolescents and adults have benefited the most by this decrease in the mortality from tuberculosis. In 1886 the group of inhabitants between the ages of 35 to 39 years showed the highest number of deaths (700 per hundred thousand). In 1911 the maximum age group was 45-49 years of age but the proportion had already dropped to 550 per hundred thousand and twenty years later (1931) it was only 255 but the age group most affected was composed of persons between 55 and 59 years. These improved statistics have been the result of a vigorous antituberculosis campaign waged since the World War in the city of Paris and its suburban territory. Moine praises the campaign that has been carried out in the United States, Holland, Great Britain and Germany since 1900. In

France the decline in deaths from tuberculosis has been twice as high during the past thirteen as in the preceding thirty five years, which is the most eloquent tribute to the value of anti-tuberculosis efforts.

Pasteur Vallery-Radot Elected Fellow of Academy of Medicine

The distinguished internist and grandson of Pasteur was elected a fellow of the Academy of Medicine at its June 9 meeting in place of the late Professor Netter. Pasteur Vallery-Radot is associate professor in the University of Paris Medical School and attending physician to the Paris (free) hospitals. He was a pupil of the late Professor Widal, under whose supervision his first research work was undertaken. He is especially known for his study of anaphylactic shock and its relation to asthma.

Homage to the Dermatologist Professor Darier

The French Society of Dermatology and Syphilography will devote one of its coming meetings to celebrate the eightieth birthday of its internationally known member Professor Darier. A monograph by the latter on the history of dermatology during the past fifty years, which was read in abstract at the Budapest congress, will be printed and presented to Professor Darier as a token of appreciation of his distinguished services to this specialty by the society. Those who desire a copy of this monograph can obtain it by sending 30 francs to Georges Masson, Esq., 120 Boulevard St. Germain, Paris.

BERLIN

(From Our Regular Correspondent)

July 10, 1936

Congress of the Society of Internal Medicine

As previously reported, this year's congress of the German Society of Internal Medicine began by meeting in joint session with the Nature Cure physicians. Professor Siebeck, internist, of Berlin, addressed the combined gathering on "The Treatment of Cardiac Weakness." Particular interest attaches to his lecture because of its subsequent discussion by the Nature Cure physicians. Siebeck in his opening remarks emphasized the value of a correct diagnosis as a foundation for any course of therapy. The anamnesis provides the best criterion of function, since from it the physician may ascertain whether or not the patient is equal to the demands of his daily routine. A multitude of factors are involved in the pathogenesis of heart failure and none is of greater importance than the state of blood perfusion in the coronary vessels.

The ultimate result of a course of therapy will not depend on any one medicament but on the medical supervision of the patient. There should be three stages of treatment: (1) relaxation and quieting of the patient; (2) restoration of functional capacity by exercise and added burden; (3) reintegration of the patient into his daily routine. Often hospitalization alone may satisfy all the conditions necessary for a genuine rest. Next there is the dietary regimen to be initiated, the daily fluid supply should not exceed 200 cc. five times. Important, too, is restriction of the salt intake. After such measures as rest in bed and restricted diet have been instituted heart medications may be administered but only in "critical" cases should the use of medications precede the other measures. Venesection or a mustard pack often affords some relief. Digitalis is effective only for insufficient hearts, the output of which it increases while at the same time retarding the beat. The blood perfusion is thus relatively improved. The favorable effect of digitalis is most pronounced in tachycardia. Mitral insufficiency frequently responds well to digitalis but mitral stenosis often reacts unfavorably because of mechanical conditions and the same may be said of aortic insufficiency. Treatment

digitalis may likewise be indicated in coronary sclerosis, and hypertonia if cardiac weakness is present. The prophylactic use of digitalis prior to operations is not justified. It is better to administer the glucoside in small doses at short intervals than in one large dose. The total quantity that may be necessary cannot be estimated *a priori* and must be determined by careful observation of the patient. This therapy should be supplemented by the administration of diuretics, since these exert an influence on the tissues. An acidotic condition of metabolism favors diuresis.

In the second and third phases of the planned therapy, the supply of fluid and of salt must still be held down. Two or three grams of salt may be added to the saltless regimen, but "more restricted" days should be temporarily interpolated. During the later phases exercise will assume the leading role together with massage, graduated respiratory exercises and gymnastics. Overexertion must be avoided. Exercise therapy should also include carbon dioxide baths.

After improvement has taken place in functional capacity, the third stage of treatment may be begun. To avoid too abrupt transition, the patient should now be placed in a work camp where he gradually may become accustomed to exertion. This is better than keeping the patient in a convalescent home, where he will probably obtain too much rest and insufficient opportunity for exercise.

Siebeck's emphasis of certain points suggests that his views do not coincide with the well known pretensions of the present government of Germany. In the discussion that followed, Katz of Stuttgart, one of the best known spokesmen of the Nature Cure group, made the forthright and emphatic declaration that, for Nature Cure therapy, a knowledge of the etiology of a disease was of slight importance. The Nature Cure treatment of heart disease consists of such measures as tapotement of the heart, massaging of the intestine, compresses on the heart and genitals and on the throat and arms, massage of the chest, as well as different types of baths and applications both morning and afternoon, and regimens of fruit juice. The foregoing sample of what took place at the joint session should furnish the reader an adequate picture of that gathering.

On the second day of the Internists' Congress proper, the topic of discussion was "Pulmonary Disorders Due to the Inhalation of Dust." Aschoff, pathologist, of Freiburg, led off with a survey of the self purifying power of the lungs and how it acts against stone dust. Persons dwelling in large cities all become silicotic in the course of their lives. But silicosis as a disease is encountered only among workers whose occupations entail the inhalation of substantial quantities of quartz dust over a considerable period. Although soot particles are inhaled without producing any pathologic reaction, quartz dust always gives rise to pronounced reaction in the tissues. Furthermore, it is difficult to say whether a physical irritation or a chemical surface action is involved. In cases of chronic inhalation, a phagocytosis of the quartz particles may take place in the reticulo-endothelial elements of the germinating centers and particularly in the cells of the lymph sinuses of the excretory region. Quartz particles enter the blood either through the lymph stream or by the rupture of an indurated silicotic cervical lymphatic gland into a pulmonary vein or by direct absorption into the blood capillaries.

Giese of Freiburg made a talk on pulmonary disorders caused by the inhalation of dust. The action of silicic acid influences the formation of nodule-like granulation tissue and characteristic silicotic granulomas. Different types of dust are responsible for differing formations. There is a typical papular formation which is found only after the inhalation of quartz dust. Asbestos needles become completely dissolved within the organism. Sericite, clay and feldspar dusts have never been known to cause indurations. Whereas pure quartz dust in

most cases enters quietly after a first reaction, a progress of the process due to the extensive formation of granulations appears if a mixture of dusts containing other soluble types is inhaled. Not all accompanying dusts aggravate the unfavorable action of the quartz dust, coal dust even appears to mitigate the effect of the quartz. Among general manifestations that occur in advanced cases of silicosis are emphysema and hypertrophy of the right side of the heart. So-called supplementary tuberculosis plays an important part in silicosis by depleting the resistance of the silicotic lung, and rapid deterioration may accordingly take place within the cavity. Endogenic reinfection also may be an important factor in the disease. In animal experimentation, tuberculosis with coexistent silicosis has been found to pursue an unfavorable course. By silicotic action in the tissues, a tuberculosis of the lymph nodes or a healed first manifestation may again be rendered active. In comparison with these internal factors in the development of tuberculosis, the external factors are of trivial importance.

A consideration of the various types of dust is likewise essential for a clinical study of dust diseases, according to another speaker, Professor Boehme of Bochum. Among the mild, nonprogressive comoses he reckons those produced by soot, pit coal, graphite, corundum, carborundum, metal dust, kaolin and ferric oxide. Siliceous dust, on the other hand, is responsible for progressive pulmonary fibrosis. If the latter condition follows the inhalation of asbestos needles, the pathogenesis may be explained as a disintegration of the pulmonary tissues by the noxious silicic acid, which substance is formed from the gradual dissolution of the asbestos particles. Boehme then specified as clinical symptoms dyspnea, emphysema and the dextro type electrocardiogram, the levo type also is encountered, however. After a ten year interval about 50 per cent of the milder cases evidence marked deterioration even when the patient has foregone his hazardous occupation. Cases of severer type silicosis are almost invariably progressive, particularly during the first years. Some 50 per cent of persons attacked die within five years. Silicosis is presented for the most part by men who have been engaged in the contaminating occupation for considerable periods, in stone cutters the disease appears after some twelve and one-half years, whereas among other workers, quartz crushers for example, it may appear as early as from one and one-half to two years after the beginning of occupational activity. An inherited predisposition may be assumed, since a high incidence has been established in a number of families. Other families, however, remain free from the disease. In view of the inability to combat silicosis, all possible prophylactic measures must be utilized. These should include examination of the applicant at the time of his employment, periodic follow-up examinations, frequent rotation of tasks, and industrial hygienic regulations.

Throughout the protracted discussion, silicosis was clinically considered not as a purely organic disorder but as a disease of the entire organism. Schlomka of Bonn pointed out the obvious influence of silicosis on nutrition, examination of 1,500 stone cutters disclosed a tendency to take on fat to be an indication of the disease and a result of the action of the noxious dust.

On the third day, Fritz Schellong of Heidelberg submitted a paper on "Electrocardiographic Diagnoses in Disturbances of the Heart Muscle." The speaker described a new procedure that helps determine the electrical axis of the heart by direct registration of changes during the heart beat. A "vectorgram" is obtained from which it is possible to establish axile alterations. A spatial vectorgram may also be composed by biplanar exposure and in this way it is possible to correlate different parts of the leg with the activity of particular regions of the heart muscle. Pathologic changes in separate regions can thus

be plainly represented and a functional diagnosis made. Schellong reaches the conclusion that, according to the sum of clinical electrocardiographic aspects, similar changes in the electrocardiogram may be interpreted in wholly divergent ways. The discussion of this report elicited numerous important details.

Of the other papers, which were concerned with the most diverse questions, a few may be briefly mentioned. Pannhorst of Greifswald has found that the following determination with regard to conjugal diabetes sheds light on the question of the hereditability of that disease. If two parents are afflicted with diabetes or if one parent is so afflicted and the other possesses a familial predisposition toward the disease, 15 per cent of the descendants will present diabetes, whereas if the disease is present in but one parent, only 1.5 per cent of the descendants will be afflicted.

Gänsslen of Tübingen spoke on his treatment of pernicious anemia. By the administration of from two to four standard ampule injections of liver extract he was able completely to rehabilitate a severely anemic hemogram within a period of from six to ten weeks. By the use of this small and infrequent dosage he had achieved favorable results in twenty-one cases. This proves that for many patients the more frequent injections are unnecessary. Besides, the use of this method effects an extraordinary reduction in the cost of treatment. Gänsslen found that precisely the most severe anemias react favorably to small doses of extract. A single injection must needs produce a decided change in the blood formation and this fact is a useful criterion whether or not the extract is effective. A second injection is administered when the increased hemoglobin content has again become stationary.

The internists concluded their congress by participation in the convention of the German Roentgen Society.

ITALY

July 15, 1936

Sanitation in Ethiopia

The public health office now organized in Italian Addis Ababa is provided with chemical and bacteriologic laboratories and offices for administration of supplies to be used in work of sanitation and prevention of diseases. Hygiene and sanitation, all through the country, is supervised by the personnel of the public health office. Addis Ababa is considered as if divided into several zones, each of which is in charge of a physician assisted by a veterinary. The capital of the empire has a special department of hygiene which is in connection with a hospital for isolation of cases of contagious diseases, branches for the improvement of hygiene of the soil and squads of Italian sanitarians and of Italians and natives working on disinfection and vaccination. The Menelik Hospital with all its departments is now a hospital for isolation of patients suffering from infectious diseases. A central post for first aid and a department for obstetrics and municipal outpatient hospitals in connection with antisyphilitic and antituberculous dispensaries have been established. The ex-Swedish Hospital as well as the hospital which was formerly in the hands of the members of the British military ambulances has been placed in the hands of the board of directors of military sanitation. The Fulut Naka and Gullale hospitals and the Sudan Interior Mission the American leprosarium, all of which have been managed by American missions are authorized to continue functioning with the collaboration of the public health department. Groups for detection and treatment of patients suffering from infectious diseases are no longer organization. Regulations have been provided making free the administration of treatments in cases of snake bites and compulsory free vaccination and also for the con-

servation of hygiene of the soil, housing, food, water, milk, live stock and market meat supply. Antityphoid vaccination is compulsory for the lower ranks of soldiers. The prevention and control of malaria and tuberculosis, the care of the insane, the production and distribution of vaccines, the supervision of hygiene and sanitation at the borders and the practice of pharmacy are problems that will be given attention in the near future.

The Riberi Prize

The Riberi prize is given for the best contribution to the progress of medicine during each period of five years. The prize was recently awarded to Francesco Pentinalli, professor of general pathology at the University of Florence, for his work on experimental tumors and cancer. The articles submitted numbered 275 and were written by thirty-eight aspirants from nine different countries.

Society Reunion

The first national congress of the Società di Antropologia e Psicologia Criminale was recently held at Rome. S. E. Novelli spoke on the satisfactory results obtained by the institutions for prevention and punishment of delinquency in reeducating and socially readapting delinquents. A complete actuation of the new penal laws has been made possible through the collaboration of magistrates and persons devoted to the scientific prevention and control of delinquency.

Fabbri spoke on the advisability of establishing offices for medicopedagogic consultations of children between the ages of 6 and 12 who at home or in school show antisocial and delinquent tendencies. A function of these offices will be the physical and moral guidance of those children.

Professor Falco spoke on the importance of the preservation of the biographic records of delinquents in the police department and on the significance of the records for application of the new penal laws owing to the fact that the personality of delinquents should be known for evaluation of the offense. That biographic records require the clinical study of the delinquents in the given case points to the advisability of having physicians who have specialized in criminal anthropology in the police department.

Professor Ovio-Ciancarini spoke on the technical and scientific procedures used for prevention and control of delinquency in soldiers. The sojourn of delinquents in special centers for readaptation and reeducation has given satisfactory results.

Reunion of Gastro-Enterologists

The Società di Gastro-Enterologia met recently at Rome. Dr. Valdoni reported results of studies on the stomach after an operation. His studies prove that periodic contraction almost disappears following gastric resection, while it is preserved almost without change following gastro-enterostomy. The changes of the secretory functions are manifest, especially if the examination is made some time after the operation. Following resection the gastric secretion is hypo-acid and sometimes there is anachlorhydria. If a patient suffering from postresectional anachlorhydria is given 200 Gm. of wine and a regular portion of oatmeal the stomach reacquires the capacity of secreting hydrochloric acid. Together with the increase of hydrochloric acid in the gastric secretion a bacterial flora appears in the gastric juice. The speaker verified the presence of bacteria in 60 per cent of the cases in which before administration of wine and oatmeal there was a sterile gastric juice.

Dr. Meldolesi spoke on the role of an insufficiency of pancreas in the development of progressive muscular dystrophy. According to the speaker the disease originates in the lack in the body of certain substances that are required for maintenance of the trophic conditions of the muscles and that normally originate in food products after the processes of gastric digestion.

Marriages

ALEXANDER VICTOR LYMAN New York to Mrs Elizabeth Gilbert Forsyth of Swampscott, Mass., at Princeton, N J, in July

EDWIN LOUIS LANDRY, De Quincy, La, to Miss Edna Lee Elberson of Lafayette in June

JOHN G LOHMANN to Miss Anastasia Hodgson, both of Fergus Falls, Minn, in June

WILEY E LINDSAY to Miss Ruby Eva Tallant, both of Winchester, Tenn., in July

MARION AUSTIN LOVEJOY to Miss Doris Olive Petit, both of Miami, Fla, June 16

Deaths

Thomas Beaver Holloway * professor of ophthalmology at the University of Pennsylvania School of Medicine Philadelphia, and professor of ophthalmology and formerly vice dean at the graduate school of medicine, died, August 18, at his home in Merion Station Pa, aged 64 Dr Holloway was born at Danville, Pa, March 24, 1872 He received a bachelor of science degree from Lafayette College in Easton, Pa, in 1894, and a master of science in 1897 in which year he also received a medical degree from the University of Pennsylvania Department of Medicine He was a past president and from 1918 to 1925 was secretary-treasurer of the American Ophthalmological Society and at one time edited the society's transactions past president of the section on ophthalmology of the Pan-American Medical Association, a member of the American Academy of Ophthalmology and Oto-Laryngology, the Societe française d'ophtalmologie and the Ophthalmological Society of the United Kingdom as well as numerous other ophthalmologic, neurologic, pathologic and general medical societies in this country In 1918 he was a member of the House of Delegates of the American Medical Association, and chairman of the Section on Ophthalmology from 1929 to 1930 He had been associated with the Wills Eye Hospital, was ophthalmologic surgeon at the University of Pennsylvania Hospital, consulting ophthalmologist to the neurologic department of Philadelphia General Hospital and ophthalmologist to the Pennsylvania Institution for the Instruction of the Blind, Overbrook In 1926 he was awarded an honorary doctor of science degree by the University of Pennsylvania and in 1932 was elected a member of the board of directors of the National Society for the Prevention of Blindness Dr Holloway was co author with Dr George E de Schweinitz, of "Pulsating Exophthalmos" in 1908 and contributed numerous articles to the periodical literature

Charles Gilbert Chaddock * St Louis, emeritus professor of neurology and psychiatry, St. Louis University School of Medicine, died, July 20 at the Central Hospital, of diabetes mellitus, aged 74 Dr Chaddock was born in Jonesville Mich, Nov 14, 1861 He received his medical degree from the University of Michigan Department of Medicine and Surgery Ann Arbor, in 1885 and later took postgraduate studies at the University of Munich and at hospitals of Paris During the years 1888 and 1889, Dr Chaddock resided in Germany, and in France, from 1896 to 1900 From 1889 to 1892 he was an assistant medical superintendent at the Northern Michigan Asylum now known as the Newberry (Mich) State Hospital In 1892 he became professor of nervous diseases at the Marion-Sims Beaumont Medical College now known as St Louis University School of Medicine He was secretary of the Section on Physiology and Dietetics of the American Medical Association from 1894 to 1895, was a life fellow of the American Psychiatric Association, and visiting neurologist at St. Louis City hospitals Dr Chaddock devised a method of physical examination for lesions of the corticospinal reflex paths whereby irritating the skin in the external malleolar regions produces extension of the toes which has become known as the Chaddock sign He translated "Psychopathia Sexualis (Krafft-Ebing) 1892 and Suggestive Therapeutics" (von Schrenck-Notzing) 1895, was the author of "Outline of Psychiatry and Sexual Crimes" and chapters in Hamilton and Godkins A System of Legal Medicine, and Peterson, Haines and Webster's Legal Medicine and Toxicology

Harry Coulter Todd, Oklahoma City Medical School of Maine, Portland 1900, a practitioner in Oklahoma City since 1903, member of the Oklahoma State Medical Association

past president of the Oklahoma County Medical Society professor of anatomy and secretary of the faculty, from 1904 to 1907 and associate professor of eye, ear, nose and throat from 1907 to 1910 at the Epworth College of Medicine, which later became the clinical department of the University of Oklahoma School of Medicine, where he was an associate professor and later professor of otology, rhinology and laryngology, fellow of the American College of Surgeons member of the staffs of the State University and St Anthony's hospitals and the Oklahoma State Baptist Orphans' Home, in addition to being associated with Dr E B Gleason in the latest edition of "Nose, Throat and Ear Manual," was the author of many monographs as well as books of poems, aged 62, died, June 25, of cerebral hemorrhage.

Henry Leander Bernardy, Philadelphia, University of Pennsylvania Department of Medicine Philadelphia, 1900 member of the Medical Society of the State of Pennsylvania an assistant on the dermatologic staff of Jefferson Hospital from 1905 to 1912, and formerly in the department of proctology at the Graduate School of Medicine of the University of Pennsylvania aged 59 died June 30, of coronary occlusion, arteriosclerosis and nephritis

William Henry O'Connor * Passed Assistant Surgeon Lieut Commander U S Navy, retired, Washington D C, Tufts College Medical School, Boston, 1916 entered the navy in 1920, retired in 1931 for incapacity resulting from an incident of service, retired with rank of next higher grade to that held on active list aged 45 died May 16 in the U S Naval Hospital of coronary thrombosis

Harry Beecher Baker, Taunton Mass, Jefferson Medical College of Philadelphia, 1880, member of the Massachusetts Medical Society and the American Academy of Ophthalmology and Oto-Laryngology, formerly member of the board of health and secretary of the school board of Dighton consultant to the Morton and Taunton state hospitals, aged 77, died, June 7, of arteriosclerosis

Willard Springer, Wilmington Del University of Pennsylvania Department of Medicine, Philadelphia 1874, member of the House of Delegates of the American Medical Association in 1902 and in 1917, member and past president of the Medical Society of Delaware, and the New Castle County Medical Society on the staff of the Delaware Hospital, aged 84 died, June 26

William Lane Buhrman * Chicago, University of Illinois College of Medicine, Chicago, 1923, member of the American Academy of Pediatrics, clinical instructor in pediatrics Rush Medical College, assistant attending pediatrician to the Presbyterian and Chicago Memorial hospitals aged 39, died, June 10 of coronary thrombosis and arteriosclerosis

Fount Willard Huddleston, Liberal, Kan, Hospital College of Medicine, Louisville, Ky 1906 member of the Kansas Medical Society, fellow of the American College of Surgeons, past president of the Meade-Seward County Medical Society, a founder of the Epworth Hospital, aged 53, died, June 5, of erysipelas and acute nephritis

George Elmer Malsbary, Los Angeles, Medical College of Ohio, Cincinnati 1896 at one time a practitioner in Cincinnati Ohio formerly assistant to the chair of practice at his alma mater and instructor of medicine University of California Medical Department, aged 62, died, May 25, of coronary thrombosis

Payson La Vern Nusbaum, Chicago, Northwestern University Medical School, Chicago, 1911, fellow of the American College of Surgeons, served during the World War associate in gynecology at his alma mater aged 57 on the staff of the Wesley Memorial Hospital, where he died, July 28

John Duncan Bonnar, Buffalo University of Toronto Faculty of Medicine Toronto, Ont Canada 1878 M B Trinity Medical College, Toronto, 1878 and M D in 1879, member of the Medical Society of the State of New York, aged 84, died, June 24, of cardiac insufficiency

Joe C Ambrister, Chickasha Okla Washington University School of Medicine, St. Louis, 1905, member of the Oklahoma State Medical Association, past president and secretary of the Grady County Medical Society formerly on the staff of the Chickasha Hospital aged 53 died June 29

Joseph Franklin Jenckes, Wrentham, Mass University of Vermont College of Medicine, Burlington 1882 member of the school committee, and board of health, chairman of the board of trustees of the Fiske Public Library, aged 88, died, May 18 in Providence, R I

Charles Hendry Shivers, Atlantic City, N. J., Jefferson Medical College of Philadelphia, 1872, member of the Medical Society of New Jersey, past president of the Camden County Medical Society, aged 88, died, June 28, of pneumonia, following a fractured femur.

Charles Edward Johnston, Portsmouth, N. H., Dartmouth Medical School, Hanover, 1897, member of the New Hampshire Medical Society served during the World War, formerly member of the City Council, aged 71, died, June 28, of coronary sclerosis.

Dillis Sidney Conner Φ Cannelton, Ind., Louisville (Ky.) Medical College, 1905, secretary of the Perry County Medical Society, county health officer, aged 54, died, June 25, in the Protestant Deaconess Hospital, Evansville, following an operation for appendicitis.

Elliott Coues Prentiss, El Paso, Texas, Columbian University Medical Department, Washington, D. C., 1900, member of the State Medical Association of Texas, aged 59, died, May 4, in a local hospital, of pneumonia, following a prostatectomy.

Trenouth Wright Edmonds Φ Horton, Kan., Northwestern University Medical School, Chicago, 1929, on the staff of the Horton Hospital, aged 32, was accidentally electrocuted, June 8, when he fell against the high tension wires of an x-ray machine.

George W. Barnes, Springfield, Mo., Missouri Medical College, St. Louis, 1884, member of the Missouri State Medical Association, aged 81, died, June 9, as the result of a fractured tibia sustained when he was struck by an automobile, and senility.

William Worrall Reber, Baldwin Park, Calif., University of Pennsylvania Department of Medicine, Philadelphia, 1879, at one time postmaster in Leighton, Pa., aged 80, died, May 4, of chronic myocarditis, nephritis and arteriosclerosis.

Dennis Leo Black, Lawrence, Mass., Dartmouth Medical School, Hanover, N. H., 1910, served during the World War, on the staff of the Veterans Administration, Boston, aged 53, died suddenly, June 4, of coronary occlusion.

Sherman Willard Boone, Presque Isle, Maine, McGill University Faculty of Medicine, Montreal, Que., Canada, 1887, fellow of the American College of Surgeons, aged 76, died, May 27, of uremia following myocarditis.

Heber Howe Cleveland, Portland, Maine, Harvard University Medical School, Boston, 1899, formerly member of the school board, aged 63, died, June 17, in Springfield, Mass., of coronary thrombosis and arteriosclerosis.

Horace Osler Averitt, Fayetteville, N. C., Emory University School of Medicine, Atlanta, 1929, member of the Medical Society of the State of North Carolina, aged 32, died, June 29, of acute dilatation of the heart.

Joseph Maxwell Cadwallader, Sheffield, Iowa, State University of Iowa College of Medicine, Iowa City, 1907, member of the Iowa State Medical Society, aged 52, died, May 23, of an accidental overdose of barbitol.

Thomas Henry Toynbee Wight, Carmel, Calif., Harvard University Medical School, Boston, 1901, veteran of the Spanish-American and World wars, aged 65, died, May 11, of bronchopneumonia and arteriosclerosis.

Giles Ripley Pease, Los Angeles, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885, formerly a practitioner in Redwood Falls, Minn., aged 78, died, May 27, of gastric hemorrhage.

Horace Bernard Blan, Brooklyn, New York, University Medical College, 1898, aged 59, formerly on the staff of the Kings County Hospital where he died, June 16, of carcinoma of the bladder with metastases.

Morton Myers, Akia, Alaska, State College of Physicians and Surgeons, Indianapolis, 1907, physician for the U. S. Bureau of Indian Affairs, aged 63, died, May 27, in Anchorage, of intestinal obstruction.

George Edwin Cook, St. Louis, St. Louis College of Physicians and Surgeons, 1905, member of the Missouri State Medical Association, aged 61, died, June 19, in the Deaconess Hospital of cirrhosis of the liver.

Robert Breckenridge Elderdice, McKnightstown, Pa., Cincinnati College of Medicine and Surgery, 1868, Civil War veteran, aged 89, died, June 28, of carcinoma of the liver and chronic myocarditis.

Austin Lynn Braden Wellman, Iowa, State University of Iowa College of Medicine, Iowa City, 1903, member of the Iowa State Medical Society, aged 65, died suddenly, June 22, of heart disease.

Daniel G. Cook, Holland, Mich., Detroit College of Medicine, 1894, formerly health officer, city physician and county coroner, aged 71, died, June 6, of chronic myocarditis and arteriosclerosis.

Archibald Benjamin Morrison, Brookline, Mass., College of Physicians and Surgeons, Baltimore, 1906, member of the Massachusetts Medical Society, aged 72, died, May 3, of coronary thrombosis.

John Sinclair Miller, Hugo, Okla., University of Texas School of Medicine, Galveston, 1903, member of the Oklahoma State Medical Association, aged 59, died, May 4, of cerebral hemorrhage.

James Renwick Gormley, Monaca, Pa., Miami Medical College, Cincinnati, 1893, member of the Medical Society of the State of Pennsylvania, aged 67, died, May 21, of pulmonary embolism.

Benjamin Lynn Bridges, Ellaville, Ga., Atlanta Medical College, 1895, member of the Medical Association of Georgia, aged 62, died, June 24, of typhus fever, pneumonia and acute nephritis.

Frank M. Bell, Portland, Ore., Miami Medical College, Cincinnati, 1883, aged 80, died, May 7, in the Multnomah Hospital of bronchopneumonia, arteriosclerosis and nephrolithiasis.

Joseph A. Lucas, Sullivan, Ill., St. Louis College of Physicians and Surgeons, 1899, for many years county physician, aged 71, died, May 18, of mitral insufficiency and angina pectoris.

Harry Newton Kierulff, San Francisco, Calif., State University of Iowa College of Medicine, Iowa City, 1892, aged 72, died, May 28, of chronic myocarditis and hypertension.

Howard Julian Lackey Φ Oakland, Calif., Hahnemann Medical College and Hospital of Philadelphia, 1899, aged 62, died, May 15, in the Peralta Hospital, of heart disease.

John Wilson Morrow, Marchand, Pa., Jefferson Medical College of Philadelphia, 1875, formerly member of the state legislature, aged 87, died, May 30, of nephritis.

Alfred Elder, Falls City, Neb., Northwestern Medical College, St. Joseph, Mo., 1888, aged 94, died, May 22, of injuries received when he was struck by an automobile.

William M. Thomas, Fort Worth, Texas, St. Louis College of Physicians and Surgeons, 1891, aged 74, died, May 3, of infected thrombosis and ulcer of the nose.

Philip James Shaver, San Antonio, Texas, University of Texas School of Medicine, Galveston, 1904, aged 58, died in May of pulmonary tuberculosis and nephritis.

Buford Munsey Tittsworth, Jefferson City, Tenn., Baltimore Medical College, 1897, served during the World War, aged 64, died, May 11, of pneumonia.

Egbert H. Relyea, New York, University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1907, aged 63, died, May 14, of chronic myocarditis.

Carrie E. Marvin Leiber, Oakland, Calif., Women's Medical College, Chicago, 1882, aged 84, died, May 26, of chronic myocarditis and nephritis.

Robert Ernest Pierce, Los Gatos, Calif., Boston University School of Medicine, 1879, aged 79, died, May 22, of cardiac decompensation and myocarditis.

Luther Calvin Havice, Klingerstown, Pa., Jefferson Medical College of Philadelphia, 1893, aged 66, died, May 4, of acute dilatation of the heart.

Charles C. Ramsey, Baltimore, North Carolina Medical College, Charlotte, 1907, aged 51, died, May 10, of carbon monoxide poisoning.

Sarah Van Gorden, Cincinnati, Pulte Medical College, Cincinnati, 1903, aged 62, died, May 19, of cerebral embolism and myocarditis.

James Lincoln Randall, Hattiesburg, Miss., Leonard Medical School, Raleigh, 1908, aged 56, died suddenly, May 13, of myocarditis.

Sarah J. Bebout, Norwalk, Ohio, Pulte Medical College, Cincinnati, 1882, aged 85, died, May 25, of chronic myocarditis.

James R. Robertson, Columbia, Miss. (licensed in Mississippi in 1908), aged 73, died in May of cerebral hemorrhage.

Sylvester Nash Young Ridgeto, Ont., Canada, Victoria University Medical Department, Coburg, 1888, died May 19.

Joseph McAndrew, Georgetown, Ont., Canada, University of Toronto Faculty of Medicine, 1905, aged 59, died May 15.

Andrew Jackson Baker, Monterey, Calif., Omnia Medical College, 1892, aged 76, died May 5, of heart disease.

Correspondence

HEALTH INSURANCE

To the Editor—It is to be regretted that the words "health insurance" have been so widely applied to plans that have had nothing to do with health and insure little except against monetary risks of unemployment produced by disease or accident. The real insurance of health to the individual and the community is something entirely different from the balancing of probabilities by the statistics of the actuary, to get a profit for the promoters of a special productive scheme for insurance, who embark in speculation by writing "insurance" on the chances of human death or disability. The report on the 'costs of medical care' was more clearly a movement in the field of finance. It was an exploration to find whether some of the income of the medical profession might be diverted to the profit of a new business enterprise offering "medical care" to a larger number of customers.

However, the insurance of health, to the individual and the community, is one of the greatest enterprises that is opening up to the civilizing races of the world. Italy has driven out the emperor of Ethiopia, but can the Italian people exterminate the tropical diseases as easily as they can kill off the savage tribes, which have become partly immune to those diseases. The future of empire and world dominance hangs on the establishing of real health insurance. This will require the growth of knowledge and development of customs that will overcome the dangers of destructive disease and establish a vast resource of race health. Only on this can empire builders rely for the success of their great undertakings. The words "health insurance" have recently occupied a commanding place in medical journals and popular magazines. They should be given a new, real and more important meaning than they have carried in the past.

To insure individual and race health has been, and still will be, the great work of the medical profession. Chance to speculate or make investments in the prospects of health or disease for the people may still be attractive to promoters and financiers, but the need to secure and preserve health is a permanent need for every member of the human race. It has been the real objective of the medical profession. Its importance increases with the discoveries of science and the experiences of individual living. The medical profession must give fresh thought and renewed attention to this greatest department of its labors, the most productive and honorable of its responsibilities.

The most important opportunities for teaching health come to the general physician, with each patient recovering from sickness. The child getting over an attack of indigestion or a cold can understand the good of avoiding such experiences in the future. The developing youth or business man is anxious to escape recurrences of periods of disability. Those who find their powers waning with age feel more strongly the need to defer the time when they must give up both business and amusement. At such times the doctor who has the full confidence of his patient can teach the pertinent facts about the preservation of health as they can be taught at no other time and by no other person. To use such opportunities will do more to insure health than can be done by any other outside organization or any publication of health propaganda.

Men secure the title Doctor of Medicine who may not have the sense of responsibility that must always be a part of the equipment of the complete physician. But the leaders in medicine have always recognized their broad responsibilities. Ever since the oath of Hippocrates was first written, the medical profession has sought to enforce on its members an understanding of the broad extent of the duties of the physician.

From generation to generation there have always been members of the profession who felt keenly how great was their duty to labor for the general health interests of their patients and their communities. Today there are many who never tell a patient he is well without pointing out what he can do to remain so. New relations and new means of communication give new opportunities to tell the people how they may insure health. But the greatest influence for good is exerted by the individual doctor on the individual patient or family. To preserve this influence, no form of business enterprise must be allowed to disturb or impair the close confidence and good understanding between physician and patient.

EDWARD JACKSON, M.D., Denver

HYPERVENTILATION IN ABDOMINAL SURGERY

To the Editor—In THE JOURNAL, July 25, pages 267-269, in an article entitled "Hyperventilation in Abdominal Surgery," Dr. T. J. Ryan concludes that "carbon dioxide is of no value in the prevention of postoperative pneumonia."

This conclusion is drawn from a group of 135 cases in which, at the close of abdominal operations, carbon dioxide was administered only once, for about three minutes, and a control group of 276 in which carbon dioxide was not administered.

The morbidity is reported as 22 per cent for those who received the inhalation and 14 per cent for those who did not, and the mortality as 0.74 per cent for those treated and 0.36 per cent for those who were not. Obviously, if these figures are significant they indicate, not merely that carbon dioxide is without value in the prevention of postoperative pneumonia, but rather that this treatment tends to increase the incidence of postoperative pneumonia.

In fact, however, the number of cases in which the inhalation was administered is so small and the figures for morbidity, and particularly for mortality in the treated group, are so low that the change of a single case would reverse the result. Indeed, a figure of 0.74 per cent for the mortality in a group of 135 patients indicates that there was exactly one death. Did the series stop when it occurred?

Dr. Ryan fails to mention the form of anesthesia used in either group of cases. Yet it is quite certain that the element of anesthesia is one of the most important in producing or preventing postoperative pulmonary complications. Dr. Ryan quotes two papers by me, one of which was published sixteen years ago and the other six years ago. Since the first, and even since the second, there have been distinct improvements in methods of anesthesia.

However, my views also have changed in sixteen years, and even in six years. I still believe that when ether anesthesia by the old method is used it is better to ventilate the lungs at the end of anesthesia by means of carbon dioxide rather than to leave the patient unaided to eliminate the drug through a long hour or hours.

But the main point, as I see it now, is that anesthesia and operation together lower a patient's vitality, and particularly the tonus of his muscles. Because of this lowering of tonus he cannot stand up, or sit up, or even lift his head for some time after the operation. The same lack of tonus in the respiratory muscles, particularly the diaphragm, permits the lungs to be partially deflated. If the deflation is sufficient to result in an occlusion of any of the airways, the air in that portion of the lungs is soon absorbed. Atelectasis of parts of the lungs, or even a massive collapse of one lung, develops. If infection is present, pneumonia may follow.

It is my belief, on the basis of many years of investigation, that depression of the circulation after anesthesia and operation is also due to decreased tonus of all the skeletal and visceral muscles, which permits the blood to stagnate in the tissues.

In surgical shock the consequent failure of the venous return is a more important factor than is vasomotor failure.

Manifestly these respiratory and circulatory conditions cannot be completely counteracted by merely expanding the lungs once at the end of an operation, any more than general body tonus and vitality can at this time be restored sufficiently for the patient to get up off the operating table, or out of bed, dress, and walk home. The value of inhalation of carbon dioxide consists in this. When it is used as needed repeatedly after anesthesia and operation, the effects of loss of tonus in producing pulmonary complications may be obviated.

As I presented my views on this general subject fully in the Carpenter Lecture of the New York Academy of Medicine, I refrain from further restatement of them here.

"TREATMENT OF EARLY SYPHILIS WITH ELECTROPYREXIA"

To the Editor—In THE JOURNAL, July 18, Drs Neymann, Lawless and Osborne, in their paper entitled "Treatment of Early Syphilis with Electropyrexia," state that "if external heat is used, especially if the temperature of the entire skin is raised to the same high level equal to that of the internal organs, terrifying states of delirium and dyspnea result." We desire to take issue with this statement. Since the introductory work of Simpson with the heated and humidified cabinet, the department of fever therapy of Grace Hospital has treated some 650 patients by artificial elevation of body temperature. Especially in the treatment of gonorrhea and its complications, body temperatures have been maintained at 106-107 F (rectal) for six continuous hours, treatment being repeated every other day. Patients are admitted for treatment only after a careful cardiovascular-renal examination. Preparatory treatment consists of the administration of 5 grains (0.3 Gm) of sodium pentobarbital followed by the judicious use of morphine or its derivatives. Saline solution in quantities of from 2 to 5 liters is consumed during a fever session. Being particularly interested in the mental reaction during elevated fever as contrasted with fever produced by infection, we have carefully recorded the results. The majority of patients experience a complete relaxation throughout the fever session. Fifteen per cent of the patients experience a mild delirium, while less than 0.5 per cent are sufficiently excited to require termination of the fever session. Dyspnea corresponds only to the elevated metabolism and at no time has dyspnea been such as to require cessation of treatment.

J. M. BERRIS, M.D.,

M. K. NEWMAN, M.D.,

Detroit

[The letter was referred to Dr. Neymann who replies.]

To the Editor—We do not sponsor any particular type of fever-producing machine. We have stated repeatedly that the skill of the physician and nursing personnel is far more important than the method employed. Terrifying states of delirium and dyspnea were frequently experienced with our patients when the entire skin surface was raised to the same high level of temperature as the internal organs averaging 42 C (107.6 F). By the entire skin surface we mean the scalp, face and neck. Moreover, it should be noted that the patient at the same time breathed hot air at a temperature ranging between 54.4 C (130 F) and 71.1 C (160 F). These are facts and not theories.

It is interesting to note that the investigators at the Grace Hospital in Detroit have experienced 15 per cent of mild

deliriums. In our experience with penetrating heat we have rarely observed the occurrence of delirious states, though we have given thousands of treatments. The incidence of delirium in our series is certainly less than 5 per cent. We rarely resort to hypnotics and give morphine and its derivatives only to truly psychotic individuals. Perhaps the particular technique employed at the Grace Hospital necessitates the use of sedatives and hypnotics and these, in conjunction with high fever, produce this really unusual number of deliriums.

CLARENCE A. NEYMANN, M.D., Chicago

A CONFERENCE ON MARRIAGE AND FAMILY PROBLEMS

To the Editor—The changing trend in medicine and education was shown by the recent conference on teaching of Marriage and Family Problems, held at the University of North Carolina, Chapel Hill, N. C., July 6 to 11, under the direction of Prof. Ernest Groves of the sociology department. The important part the physician must assume in the teaching of sex education, preparation for marriage and family adjustments is evident from the list of topics presented by physicians at this conference. The conference stressed the necessity for the physician becoming aware of the sociological problems of medicine, which form part of the problems presented by preventive medicine and mental hygiene. The nonmedical marriage counselor is attempting to advise on matters of sexual adjustment, family relations and behavior problems and even contraception because heretofore the physicians have largely ignored these phases of public health. The gynecologist, psychiatrist and obstetrician in scattered instances have been cognizant of these problems in treating their patients. The conference brought out the need for scientific sex information concerning human beings and felt that college courses should make such information available to all students who may request such information. For such purposes it is necessary to correlate medical facts with sociological application, which is the newest approach to the teaching of sex education, marriage preparation and family relations.

For marriage advice the ideal arrangement is for the family physician to be properly trained to serve as a competent marriage counselor, calling on specialists when necessary. May I call attention again to the necessity, therefore, of including such training in the regular medical school curriculum, as was also pointed out recently in the article on preparation for marriage by Dr. Robert L. Dickinson in the *American Journal of Obstetrics and Gynecology* 31: 165-168 (Jan.) 1936.

The wide field of topics discussed is shown by a list of the papers presented both by physicians, sociologists, psychiatrists, psychologists and teachers.

Physicians presented the following:

Medical Aspects of Preparation for Marriage, Dr. Eva Dodge Winston, Salem, N. C.
Problems of Pregnancy That Need to be Understood by Married People, Dr. R. A. Ross, Duke University Medical School, Durham, N. C.
Premarital Mental Hygiene Factors in Marriage Adjustment, Dr. Malet E. Goudge, Durham, N. C.
Preparation of College Students for Marriage and Life: A Presentation of Courses Given at New York University Heights Center, Dr. Mar Pichel Warner, New York.
Medical Viewpoints on the Safe Period, Dr. Benjamin Varner, New York.
Problems of Child Care, Dr. A. H. London, Durham, N. C.
What Should a Medical Premarital Examination and Interview Include? Dr. Malet Pichel Warner, New York.

Nonmedical papers presented were as follows:

The Psychology of Childhood—Emotional Development, Fay Allen.
Intellectual Development—Behavior Problems, Phyllis Barlow, Philadelphia Child Clinic in a Clinic, Philadelphia.
The Family and the Law—Marriage and Divorce, Harry D. Fox, Ford, New York.
Food Needs and Problems of Children, Katherine Hottel, Virginia Medical College, Richmond, Va.

Common Problems of the Married Woman Gladys Hoagland Groves author Chapel Hill N C
Marriage Problems Due to Woman's Changing Status Ernest R Groves professor of sociology University of North Carolina
Education for Family Life for High Schools Sadie J Swenson Technical High School Springfield Mass

The students and their parents are demanding adequate preparation for improving marriage and family relations, and the timorous colleges can well follow the courageous example of the University of North Carolina, under the leadership of Professor Groves

I am submitting this as a physician who is actively engaged in the practice of medicine and who deals daily with many of the problems mentioned I believe this information will encourage social workers, teachers and parents to urging their physicians into becoming actively interested in these problems

MARIE PICHEL WARNER, M.D., New York

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST

ALBUMIN IN URINE

To the Editor—In THE JOURNAL Oct 12 1935 page 1210 appears a query and answer regarding employment examinations and the establishment of standards including one for limits of albumin in the urine we are mentioned as being suppliers of the equipment Is the limit of 10 mg of albumin per hundred cubic centimeters of urine universally considered as a maximum where the line shall be drawn at least as a preliminary step? Is this limiting figure recognized by those medical examiners who are handling the employment work for some of the larger concerns? Do you know of any industrial concerns or associations that have attempted to lay down standardized examination specifications which include the albumin phase? Where can such information be obtained? We are greatly interested in this special field of employment for our albumin standards I should like to be sufficiently informed so that I might approach the medical director of any company and point out that there are limits to albumin and that such determinations should be quantitative that 10 mg per hundred cubic centimeters of urine and below may be disregarded that 20 30 and 40 mg may mean so and so

W New York

ANSWER—These pertinent questions are difficult to answer So far as one can ascertain without extensive inquiry by questionnaire, there are no generally accepted criteria in the field of employment examinations Each industrial medical department has created its own standards and these vary in different industries and for different types of employment The expected duration of employment, the type of work to be done and the age of the applicant are all variable factors In the original query, the criteria for the employment of motor vehicle drivers was mentioned specifically and in such instances, when the lives of passengers and others depend on the driver's good health, rigid qualifications are justified Such high requirements would not be reasonable, however, in the acceptance for temporary employment of labor, as in nonhazardous construction work

The limiting figure of 10 mg of protein per hundred cubic centimeters of urine as normal is derived from the general practice of life insurance medical rating and from clinical experience For example, the finding of 10 mg of albumin per hundred cubic centimeters of urine intermittently would not increase the rating (or the presumed life expectancy) under age 45 but over this age it would increase the premium rate 25 per cent On the other hand, 20 mg or more not constantly

present at any age would justify an increase in premium rate of from 25 to 50 per cent or even rejection of the risk If the albuminuria is constant, that is, found uniformly on repeated urine examinations, the increased rating would be still higher and many of these applicants for insurance would be rejected Additional impairments, such as hypertension, would warrant rejection without repeated urine examinations

It is realized, of course, that the objectives of examinations for life insurance and for employment may be quite different If, however, the industrial concern has existent a "sick benefit" service or a pension plan, the problems become similar The similarity of these two fields of prognostic medicine depends on whether or not the employment is expected to be permanent or transient If the objective of employment examinations is merely to weed out those who are particularly poor risks from the point of view of accidents (reducing losses under the employer liability laws), the limit of 10 mg of albumin per hundred cubic centimeters of urine is far too rigid Clark and Drinker (Industrial Medicine, National Medical Book Company, New York, 1935) do not include urinalysis in the routine of employment examination They state that "applicants should be rejected on physical grounds only when their employment would make them a menace to themselves, to others or to property" This definition of the criteria for rejection for employment may be far too liberal if the employer is interested in the health of his employees

Even profuse proteinuria, especially in young persons, may exist without seriously affecting their risk or longevity, as in orthostatic albuminuria The proof that albuminuria is orthostatic in character may mean acceptance for employment instead of rejection The medical service of employment offices cannot afford to take the time necessary to determine the clinical significance of albuminuria when found in a prospective employee, particularly at a time when there is a superabundance of unemployed labor Although at times the consequences may prove most unfair to a few individuals, it is necessary to create arbitrary criteria of acceptability There is no uniformity of opinion concerning these as yet It may be wise also to recall that considerable renal impairment may exist with but traces (much less than 10 mg per hundred cubic centimeters) of albumin in the urine In these instances, however, physical examination, including determination of the arterial tension, should reveal disease The problem of economic reconstruction and employment of those physically handicapped has recently been considerably advanced in Philadelphia (Stroud, W D The Rehabilitation and Replacement in Industry, THE JOURNAL, Nov 2, 1935, p 1401)

Extensive inquiry among the offices of medical examiners of the larger industrial concerns might yield pertinent information

MAGNESIUM SULFATE INTRAVENOUSLY IN HYPERTENSION

To the Editor—Please give details as to the use of magnesium sulfate intravenously in the treatment of hypertension also references

PAUL K JENKINS M.D. Miami Beach Fla

ANSWER—The pharmacologic actions of magnesium sulfate are different when injected intravenously or intramuscularly from the action when administered by mouth (Meltzer, S J M Rec 68 965, 1905) There is no catharsis, but a cerebral depression and reduction in muscle tone (Meltzer, S J Inhibitory Properties of Magnesium Sulfate, THE JOURNAL, March 25, 1916, p 931) Anesthetic properties develop when it is injected and these effects are apparently associated with reduction of the spinal fluid pressure and the bulk of the brain, presumably because of cerebral dehydration (Weed, L H, and McKibbin, P S Am J Physiol 48 512 [May] 1919 Foley, F E B, and Putnam, T J Am J Physiol 53 464 [Oct] 1920 Auer, John, and Meltzer, S J J Exper Med 23 641 [May] 1916) Because of the cerebral effects and because of the antitetic action intravenous magnesium sulfate has been employed especially in the management of eclampsia and the late intoxications in pregnancy (Adair, F L, and Stieglitz, E J Obstetric Medicine, Philadelphia, Lea & Febiger, 1934) It is then administered as a hypertonic solution (10 per cent) in doses of about 10 cc. every four hours for six or eight doses (McNeile, L G and Vruwink, John Magnesium Sulfate Intravenously, THE JOURNAL, July 24, 1926, p 236 Bowman, E C South M J 18 351, 1925 Blackfan, K D and Hamilton, B Boston M & S J 193 617 [Oct. 1] 1925) Remarkable control over eclamptic convulsions have been reported, with an associated reduction of the arterial tension In view of the oft reiterated suggestion that eclamptic convulsions are etiologically correlated with cerebral edema (Zangemeister, Ztschr

f *Geburtsh u Gynäk* 79 1, 1916 Slemons, J M Value of Blood Pressure Determinations in the Practice of Obstetrics, *THE JOURNAL*, Sept. 8, 1917, p 778) and the known dehydrating effect of intravenous magnesium sulfate, it has been assumed that the pharmacodynamics involves cerebral dehydration. Improvement of the circulation to the vasomotor center presumably accounts for some of the reduction in the diastolic tension (Baker, B M, and Bordley, James, III *Bull Johns Hopkins Hosp* 38 320 [April] 1926) The effects of magnesium sulfate are primarily expressed in relieving the hypertensive state but are without great benefit to the course of hypertensive arterial disease. Intravenous injection of magnesium sulfate is said also to aid in the absorption of retinal exudates in hypertensive disease (Lissner, H H *California & West Med* 40 330 [May] 1934)

In acute glomerular nephritis with hypertension and azotemia, magnesium sulfate is said to diminish the irritability and reduce twitching movements (Blackfan and Hamilton, cited before. Aldrich, C A *J Intern Med Soc* 25 471 [Sept] 1935) However administration of magnesium sulfate by any route to nephritic patients may be distinctly dangerous The elimination of the salt may be greatly impeded in nephritic individuals and thus elevation of the magnesium content of the blood may occur Coma due to increased plasma magnesium has been reported as occurring after single oral purgative doses of the salt (Herschfelder, A D *Clinical Manifestations of High and Low Plasma Magnesium*, *THE JOURNAL*, April 7 1934, p 1138) Magnesium sulfate is also a cardiac depressant and on intravenous injection may cause severe cardiac reactions abrupt collapse simulating a state of shock.

Despite the various favorable reports for intravenous medication with magnesium sulfate in hypertensive arterial disease, the general application of this measure would be unwise It may be justified in certain acute emergencies, such as eclampsia or when cerebral edema is presumed to exist. Hypertensive arterial disease is a chronic progressive and insidious disorder, often asymptomatic for many years, the therapeutic effects of magnesium sulfate are too transient and fleeting to be of permanent or curative value. Medication requiring frequent injection (whether hypodermically, intramuscularly or intravenously) should be limited to urgent situations, any injection (especially intravenous) is attended with some risk It has been demonstrated repeatedly that, with a few exceptions, hypertensive patients who feel relatively well will not long continue medication by injection. Long continued therapy is essential to arrest the progression of hypertensive arterial disease Magnesium sulfate should be considered a relatively dangerous drug in the presence of nephritis and/or renal functional impairment.

MERCURY IN SYPHILIS

To the Editor—What is the best preparation of mercury to use with the needle in syphilis? Is mercury by mouth efficient? If so what is the best preparation? Is it as satisfactory as mercury intramuscularly? Is mercuric succinimide efficient? I have given the succinimide one third grain (0.02 Gm.) every second or third day for two or three months without producing salivation or anything else I have given it in two-thirds grain (0.04 Gm.) doses every fifth day without causing a disturbance. Should mild salivation be caused by mercury preparations for the best results? Please omit name.

M D Pennsylvania.

ANSWER.—For intramuscular use in the treatment of syphilis the soluble and insoluble mercurial salts were in the past used quite extensively The soluble salts such as succinimide, bichloride and benzoate and the insoluble, such as salicylate and gray oil had popular vogue. During the last ten years there has been a steady decrease of the use of mercury intramuscularly because it has been found that bismuth has a higher therapeutic index a lower incidence of toxicity, and fewer local reactions at the site of injection. The therapeutic advantages of bismuth preparations over mercury preparations have been supported in the numerous studies reported in the literature.

Mercury succinimide is still used by some syphilotherapists when bismuth is not tolerated well and occasionally patients are encountered in whom a daily injection of a soluble salt such as the succinimide will produce satisfactory therapeutic effects when bismuth has failed These cases are rare however The soluble salts are absorbed quickly and likewise excreted quickly so that if the succinimide is used, daily injections should be given Mercury by mouth has no place in the treatment of early or serious complications of syphilis In the elderly person with a benign syphilis or occasionally in the patient with hepatic syphilis it may be used It is not as therapeutically efficient as intramuscular mercury The preparations used by mouth are yellow mercurous iodide in 0.016 Gm. doses or mercury with chalk in 0.055 Gm. doses.

Salvation is not an index of thorough mercurialization but is rather indicative of the fact that the patient had pyorrhea much constructive dental work with many crowns, or a "dirty" mouth before the mercurial therapy was started. Prophylactic treatment of the teeth and gums is necessary in this type of patient before the mercury is given Accordingly, mild salivation is not essential in the treatment of syphilis by mercury.

In the selection of a bismuth preparation it is advisable to choose one that has a high content of metallic bismuth. (See New and Nonofficial Remedies)

POLLEN DISTRIBUTION IN MAINE

To the Editor—In *THE JOURNAL* July 19, is a reply to a request for information about hay fever resorts in Maine The editorial answer is inadequate and appears to be based solely on an individual ragweed concentration count in the high altitude forest such as Rangeley Lakes The very extensive sea coast of Maine in islands capes and long indentations gives the heat natural sea air limitation to ragweed air pollution I regret that the public does not yet understand that highways of travel, as well as the wind carry ragweed pollen Cars are good agar plates for the collection and transportation of pollen There has been less traffic contamination as well as less wind borne contamination over mountains and forests The numerous islands and forest protected headlands on our Maine coast are nearly free from hay fever Among such headlands, almost surrounded by ocean is Eastport which has only one highway approach with little travel over it until this year Such conditions obtain at perhaps a hundred other points on the Maine coast No area east of the Rocky Mountains is zero to ragweed Its prevalence is entirely in accordance with a kindergarten knowledge of physics and geography I am pleased to state that several towns this year have made appropriations to pull up and destroy ragweed Such towns earn the right of publicity for their intelligent and in due time profitable action

CHARLES B SILVESTER, M D Portland Maine

ANSWER—The answer to Dr Albers was not "based on an individual ragweed concentration count in the high altitude forests such as Rangeley Lakes" It was based on the results of two seasonal pollen studies made at Rangeley Lakes, together with the results of studies made in the Gaspé Peninsula at Eastport, Maine (see answer), at Bar Harbor and at Boston. The conclusions drawn also involved experience gained in many years of atmospheric pollen study in more than a hundred localities in North America, including some twenty points along the Atlantic and Gulf coasts The answer did not attempt a comprehensive discussion of the hay fever resorts in Maine but was an effort to select, by means of available information, the most nearly pollen free point affording first class hospital facilities The protest seems to be concerned mostly with (a) defending the merits of the numerous coastal hay fever resorts of Maine, (b) introducing a new theory of pollen distribution.

(a) No statistics or other proof is offered to support the claims made, and no definite place better than the Rangeley Lakes area is suggested unless the plea for Eastport is to be so interpreted By rereading the published answer it will be seen that Eastport was not condemned On the contrary its merits were weighed on the basis of comparative statistics

As to the amount of hay fever in the sparsely settled islands and headlands of the Maine coast, conflicting reports have been published for the last sixty years (See annual lists of places reported as "immune not immune and partially immune," published by the United States Hay Fever Association from 1874 to the present time.) This is primarily a clinical approach to the problem—a trial and error method—and one that has never proved very satisfactory (Wyman Morrill *Autumnal Catarrh*, [Hay Fever], Cambridge, Mass, Riverside Press 1876, p 57) It will doubtless be continued indefinitely by those who do not fully accept the thesis (Rackemann, F M, and Smith L B *Ragweed Hay Fever Symptoms and Pollen Concentration Compared* [1930] *New England J Med* 204 708 [April] 1931 Hopkins, Marjorie *Effect of Weather Variations upon the Symptoms of Hay Fever Patients* *J Allergy* 2 145 [March] 1931 Feinberg S M, and Durham O C *Hay Fever in Chicago and Suburbs Clinical Field and Air Observations* *Illinois M J* 63 464 [May] 1933) that hay fever symptoms vary in intensity directly with the quantity of pollen encountered and by those who doubt (Rackemann F M *Clinical Allergy—Asthma and Hay Fever*, New York, Macmillan Company 1931 pp 253-258 Vaughan W T *Allergy* St. Louis, C V Mosby Company 1931 p 110) that the pollen contact of sensitive persons may be determined with practical accuracy by the use of atmospheric pollen slides

The inquirer seems particularly anxious that due publicity shall be given to the several towns which have this year made appropriations to pull up and destroy ragweed He should have designated these places But every one knows that appropriations are not always adequate or effective One city aside several thousand dollars for ragweed extermination this year but the fund was used up in the first two days of it

campaign and before any appreciable inroads had been made on the ragweeds. Another large city recently spent in one season approximately \$1000 per square mile of its area (\$165,000 in all) with the purpose of making the city a hay fever refuge. No doubt a number of pollen-sensitive people who lived near extensive weed patches were slightly benefited but the total result was disappointing in that the pollen slides exposed by the United States Weather Bureau revealed more ragweed pollen in the air than during any previous season of record.

The variation in kinds and quantities of pollen inhaled by sensitive persons engaged in ordinary pursuits depends on many varied and elusive factors, and an elementary knowledge of geography and physics is not sufficient to measure the end result. Atmospheric pollution is not a local affair as proved by the large amount of atmospheric pollen found in forested areas as much as 75 to 100 miles from weed-infested areas (Durham O. C. Pollen Studies in Selected Areas, *THE JOURNAL*, April 27 1935, p 1486).

On the basis of the arguments advanced in this protest one would readily conclude that the islands off the North Carolina or Texas coast would be perfect refuges for hay fever victims, but atmospheric studies have proved the exact opposite. A sea coast location has the admitted advantage of ocean breezes but these are not constant and if the hinterland is an agricultural area, nothing can stop pollen laden winds from blowing over the coast. Thus, Atlantic City is an excellent hay fever resort when the wind blows from the ocean but a very poor one when the wind blows from the land. Miami, Fla. has absolutely no pollen in the air when the wind blows from the ocean and almost none when the wind blows from the land because the Everglades have comparatively few farms and almost no ragweeds.

(b) The theory advanced, namely, that highways of travel are important sources of pollen transport, is new and original. No proof is offered and no explanation given as to how an "agar plate" even of gigantic size could collect more than comparatively insignificant amounts of pollen, or how after collecting it could then liberate it again in an otherwise pollen-free locality.

The lower several thousand feet of air contains during the pollen season large amounts of pollen (Scheppegrell, William. Airplane Tests of Hay Fever Pollen Density in the Upper Air, *M J & Rec* 119 185 [Feb 20] 1924). A cubic mile of air on days of moderate ragweed contamination contains about a pound of ragweed pollen (approximately 200 billion pollen grains). Heavy concentrations of nearly a hundred pounds per cubic mile have been recorded. With ordinary wind velocities of from 10 to 20 miles an hour it can be seen what enormous amounts of pollen are quickly moved about. No artificial carrier could possibly approach this result.

SUNBURN OINTMENTS

To the Editor—I have used numerous ointments for treatment of sunburn among them boric acid ointment and hutesin picate the only disadvantage being that they soil the clothes or discolor them. Now what ointment could you recommend that would be effective and yet not possess these obnoxious features? There is a widely advertised ointment that claims such features (Noxzema) yet from some of my patients who have used it I have heard both praise and condemnation of the product. Has this particular ointment been investigated by you as to the possible ingredients? Please omit name and city. M.D. New Jersey

ANSWER—Various ointments can be used advantageously in the treatment of sunburn. Five or ten per cent boric acid in cold cream an ointment containing solution of aluminum subacetate 1 part, wool fat 2 parts and zinc paste (without salicylic acid) 3 parts, and, in severe sunburn, tannic-acid containing ointments, are of value. The use of liquids or lotions obviates some of the objectional features of ointments and are also effective. Calamine lotion to which has been added 8 to 10 per cent of solution of aluminum subacetate, or solution of aluminum subacetate diluted with 15 parts of cold water may be used as a compress or local applications of equal parts of olive oil and lime water to make an emulsion.

The American Medical Association has never published anything on "Noxzema" nor has it been examined by our own Laboratory. It was however, analyzed by the chemists of *Good Housekeeping Magazine* who reported:

The sample appears to consist essentially of an emulsion of water calcium and ammonium soap with some saponifiable oil or fat. It contains also small amounts of borax glycerin and volatile oils (camphor oil of cloves).

Noxzema has no particular advantages as an ointment for sunburn over any mentioned and has all the disadvantages of an ointment as far as greasiness and messiness are concerned.

CHANGES IN TASTE SENSATION

To the Editor—A man aged 59 married appears to be in perfect condition for his age. His only complaint is that any starchy food or sugary taste brassy and unpalatable. He is a traveling salesman active with a good appetite and full of energy. There is no loss of weight and no symptoms of any kind appear except as mentioned. The patient is about 6 feet (183 cm) tall and weighs about 190 pounds (86 Kg). He is active in gait and gesture. The tongue is slightly coated. A few carious teeth have recently been filled. The throat shows no changes of note. Endocrine neuromuscular skin bone and joint examinations gave no observations of note. The blood pressure is 158 systolic 98 diastolic. The pulse is regular and the rate is 74 a minute. The heart shows normal rhythm and no murmurs. The urine contains no albumin or sugar the specimen is clear. The abdomen shows average peristalsis no masses and no tenderness. The bowels move fairly well. The patient takes an occasional laxative. He has recently taken salts with copious evacuation and no improvement in the condition of which he complains. The lungs are normal. While the foregoing does not represent all the observations that could be obtained it will be stated that no blood chemistry and no other laboratory or x-ray data have been sought since the patient does not feel sick and does not care to undergo extra expense unless it is justified in his own mind. Please omit name. M.D. Mississippi

ANSWER—There is no organic disturbance that would affect taste, particularly for starches and sugars. Sometimes arteriosclerotic involvement of the tongue and of the mucous membranes produces burning sensations and changes in taste.

POISONING POSSIBILITIES FROM BUFFING AND POLISHING ADJUVANTS

To the Editor—As plant physician of the Wright Aeronautical Corporation Paterson N. J. I am desirous of obtaining definite information as to the effects (poisonous if any) of the following material on the human being: tripoli manufactured by the Plating Products Company Hansen VanWinkel and Nunning & Nunning of Newark N. J. red rouge manufactured by the same firm mutton tallow manufactured by the Chandler Chemical Company of Cleveland and emeric (grade 126) and (grade 150) manufactured by E. Reed Burns of Brooklyn. These substances are used at our plant mostly by polishers who are obliged to handle these substances and many of the men claim that they unconsciously insert their fingers in their mouths and also touch the moist surfaces of the mucous membranes of the nose and eyes. What I am anxious to know is what effect if any these substances have on a person when it is handled in this manner also what effect if any it would have if part of it is inhaled. Do the substances contain anything poisonous or injurious? FRANK A. BARLOW M.D. Paterson N. J.

ANSWER—Since buffing and polishing adjuvants as manufactured by various concerns are quite similar as to chemical constituents, it is desirable that this answer apply to all such products rather than to those of any one manufacturer. Tripoli is a cryptocrystalline siliceous mineral derived in this country chiefly from southern Illinois and southern Missouri. Because of its peculiar electrostatic properties, it does not readily lend itself to dust formation, even when in fine, dry particles. Although silicosis caused by this material is practically unknown, it is believable that if the substance actually entered the lungs in sufficient quantities and over prolonged periods of time, silicosis would be produced. This substance, as used as a polishing agent, is ordinarily combined with other substances in the following approximate formula: tripoli, 50 per cent silica, 30 per cent, stearic acid, 10 per cent, paraffin (or other) wax, 10 per cent.

Red rouge is red iron oxide (Fe_2O_3). This substance is used extensively in the polishing of plate glass. Gross exposures associated with glass polishing and in the manufacture of this rouge have provided no evidence of its being a source of dusty lung disease in any form. A large number of roentgen examinations have been made of workers highly exposed in dusty areas. This is borne out by the experiments of the United States Public Health Service. A governmental report (Miller J. W., and Sayers, R. R. The Response of Peritoneal Tissue to Injected Dusts, *Pub Health Rep* 49 80 [Jan 19] 1934) states that "the response of the peritoneal tissue to this dust is therefore one of inertness." As used in polishing and buffing this red rouge may be incorporated with tallow, waxes, fatty acids or other bases. Such substances, rather than the rouge itself, may occasion a dermatitis.

Mutton tallow has long enjoyed extensive household and professional use in various emollients. Notwithstanding, it may become rancid and lead to a dermatitis or, in the absence of rancidity, may prove to be the source of comedones.

Emery (aluminum oxide Al_2O_3), or carborundum (silicon carbide SiC), as used in polishing, may give rise to much dust but again it may be stated that such dusts are relatively innocuous compared with the highly injurious action of silica.

Unmentioned in this query but much used in polishing are French chalk, rottenstone and other calcium minerals. None of these have led to genuine dusty lung diseases. At times there

may be used in the polishing of chrome plated materials a chrome-containing agent. This chromate is highly irritating and has led to the production of characteristic chrome holes" and chrome dermatitis. This discussion tends to exculpate practically all the substances mentioned in the query as being without harmful properties except as producers of skin disease or conceivably paraffinomas. Nevertheless the occupation of polishing and buffing is to be accepted as a dangerous one. The incidence of pneumonia is high, tuberculosis at least in past decades, stands out, low grade respiratory diseases are common, postural hazards are definite, continuous vibration may lead to tenosynovitis and related disorders. In addition to the dermatitis from the greasy substances used as adjuvants to polishing, skin lesions may arise from mechanical agencies and from the glues used in the resurfacing of the polishing wheels. The polisher and buffer may perform his duties in an atmosphere laden with dust from cotton, linen, synthetic abrasives, glues, limestone and metal dust from the parts being polished or buffed, so that in the final analysis this trade is to be rated as a somewhat hazardous one.

PRECOCIOUS UNILATERAL HYPERTROPHY OF BREAST

To the Editor—A girl aged 10½ years, 52 inches (132 cm) tall, weighing 74 pounds (33.6 Kg.) had the usual diseases of childhood and a tonsillectomy in 1928. Her general health was from good to excellent. About May 1, 1935 she fell into an open manhole striking the anterior surface of the chest. No visible contusion was produced but there was pain over the chest especially the lower part of the thorax in breathing. This pain and aching continued intermittently for six weeks. About August 10 the mother noticed a slight enlargement of the left breast especially around the nipple and areola. I first examined the child at this time. The right breast showed no enlargement or development. Palpation of the left breast showed a rounded but not nodular enlargement about the size of a shelled almond loosely adherent to the nipple and areola but freely movable over the pectoralis muscle. The enlargement was moderately tender and the patient complained that even light pressure produced discomfort. About October 1 the patient was seen in consultation and examined by a general surgeon who advised watchful waiting and the application of iodine ointment for a month. November 1 she was examined by the same general surgeon who considered either the removal of a small portion of the enlargement which had now reached the size of an unshelled almond for biopsy or roentgen therapy. He decided against biopsy to avoid mutilation of the breast and to conserve cosmetic appearance in later years and suggested roentgen therapy. The advice of two roentgenologists differed and roentgen therapy has been deferred owing to the fact that one competent man advises that roentgen treatment would be useless unless a malignant condition existed and might even arrest the development of normal breast tissue. There is no involvement of the left axillary or cervical glands. I then consulted two pediatricians who after taking the history and making an examination, advised against treatment and diagnosed the case as a precocious unilateral normal development of breast tissue. No one consulted has been markedly positive in his opinion as to diagnosis and prognosis and all stated frankly that in their experience they had seen only a limited number of parallel cases. Reference to the medical literature has not been helpful. At the present time there is no development in the right breast. The left breast is visibly and palpably enlarged and if any change has taken place during the period of observation two things I believe are noteworthy: namely that at times there seems to be a slight variation in the size of enlargement as proved by inspection and palpation and fullness at times or wrinkling at times in the nipple and areola also the enlargement does not seem to be as adherent to the nipple as on early examination. No menstruation is present nor are there more than few signs that the child is approaching puberty. Naturally I refrain from advising any procedure that will mutilate or destroy what will eventually be this child's left breast both from the esthetic and the maternal angle yet if this is a malignant condition due to trauma I must advise radical surgery and must do so in the near future. Your suggestions as to diagnosis, treatment and prognosis will be greatly appreciated. Kindly omit name.

M D Wisconsin

ANSWER—The enlargement of the breast probably represents a precocious unilateral prepuberty hypertrophy. The relationship between the possible trauma and the condition of the breast is highly questionable. In addition to the precocious unilateral prepuberty development the presence of a discrete mass probably represents a state of so-called puberty mastitis. In this condition the enlargement is due to a hyperplasia of the perimammary and periacinus connective tissue and of the duct and acinous epithelium. This condition is common between the tenth and thirteenth years of life. It is usually bilateral but sometimes unilateral. It is possible, but not likely, that the patient is suffering from an actual tumor of the breast induced by trauma. The differential diagnosis depends on the exact nature of the mass. In "puberty mastitis" the lesion assumes definite and very characteristic features. The swelling forms a disklike or spherical tumor situated in the region of the nipple and areola and varying from 3 to 5 cm in diameter. If the clinical observations support this diagnosis both surgical intervention and radiation therapy are contraindicated and there

should be no treatment except careful observation. If the clinical examination of the tumor does not coincide with the classic manifestations in "puberty mastitis" and particularly if the mass shows evidence of progressive enlargement, the nature of the lesion must be established by means of biopsy. The weight of evidence in this case favors diagnosis of precocious unilateral puberty hypertrophy. The differential diagnosis of this condition is given in "Tumors of the Breast," by G. L. Cheate and Max Cutler, Philadelphia, J. B. Lippincott Company, pages 21-24.

USE OF SALINE SOLUTIONS IN THROMBOANGIITIS OBLITERANS

To the Editor—Good results have been reported with the use of intravenous injections of 5 per cent saline solution in the treatment of thromboangiitis obliterans. Will you kindly advise me as to the specific action of the solution? Please advise me also as to who first discussed the intracutaneous injection of physiologic solution of sodium chloride to test the circulatory condition of an extremity. Please omit name.

M D New York.

ANSWER—Use of intravenous injections of 5 per cent sodium chloride solution in the treatment of thromboangiitis obliterans is not regarded as a specific treatment. It is merely a means employed to hasten the development of collateral circulation when major vessels have been occluded. While the beneficial results have been noted in hundreds of cases, the mechanism by which this benefit is produced is not established. A striking increase in blood volume follows the intravenous injection of hypertonic salt solution and persists from two to four hours. Such an increase in the amount of circulating fluid within the blood vessels probably opens up capillary circulation that is ordinarily closed. It may have some stretching effect on the larger vessels. The salt injected is excreted slowly, usually requiring forty-eight hours for total excretion. It rapidly leaves the blood stream after injection and undoubtedly enters the body tissues. The accompanying water thus added to the soft tissues combats the tendency to dehydration and perhaps promotes the development of collateral circulation. The intracutaneous injection of physiologic solution of sodium chloride to test the circulatory condition of an extremity was proposed by Milton B. Cohen. The article appeared in *THE JOURNAL*, May 23, 1925, p. 1561.

TREATMENT OF PUS FROM URETHRAL FISTULA

To the Editor—What treatment would you recommend for a discharge of pus (now negative on smear for gonococci) from an opening one-eighth inch away from the meatus? Gonococci were present in a urethral smear, but the discharge has ceased and urinalysis is also now negative. Nine injections of Corbus Ferry Filtrate (Parke Davis & Co.) intracutaneously weekly have been given the last two being each 0.5 cc in quantity.

M D, New York.

ANSWER—It usually is possible to clear infection from these channels by the injection of the milder protein silver solutions at frequent intervals. To do this a small probe-pointed needle is passed to the depths of the sinus and the fluid injected as the needle is withdrawn.

At times these channels can be destroyed by passing a fulgurating wire to their depths and turning on the current.

If a para-urethral sinus is sufficiently close to the urethra the intervening mucous membrane can be severed. Care should be taken that the incision extends completely to the depth of the sinus, otherwise an ideal structure for the perpetuation of a gonorrheal infection is left, should the patient again acquire the disease.

BILATERAL SCIATICA

To the Editor—I have a patient who because of a bilateral sciatica is able to get relief only by lying with his hips in an acutely flexed position (the thighs flexed on the abdomen). I shall appreciate it if you will advise me as to what apparatus will retain his thighs in this position during sleep. Is there any recent method of treatment that might relieve or cure his condition? Are there any men who specialize in this? If so will you please give me their names? Please omit name.

M D Maryland

ANSWER—When a patient is suffering from a severe and resistant sciatica and particularly from a bilateral sciatica a lumbar puncture should be made to ascertain whether there is an intraspinal pathologic condition. This puncture should be made low preferably between the fifth lumbar vertebra and the sacrum as the spinal block may be in the lower portion of the canal pressing on the roots of the cauda equina. The fact that the patient gets relief only in acute flexion of the thighs is not in keeping with the ordinary symptoms of sciatica.

due to pathologic changes in the lower lumbar spine or sacro-lumbar junction. The position can be maintained only by balanced traction, placing the thighs in flexed position on an inclined plane. However, in view of the bilaterality and the unusual position of relief, the question of intraspinal pressure should by all means be settled first. Any experienced orthopedic surgeon ought to know how to manage a case of simple sciatica. If intraspinal pathologic change is proved or strongly suspected, the services of a neurologic surgeon should be enlisted.

TRAINING INFANTS TO BLADDER AND BOWEL CONTROL

To the Editor—In *Time* February 17 under Medicine Mrs Gruenberg of the Child Study Association of America makes the following statement in part: "There has been a definite reaction against the practice of beginning to train infants to bladder and bowel control during the first weeks of life. Specifically we suggest that mothers should not begin trying to train their children in bowel control much before the age of eight months, bladder training fifteen to seventeen months is early enough. This is the first time I have read this opinion. Is it accepted as best at the present time? If so I wonder what is the danger if any of starting earlier."

ARTHUR B. DAVENPORT M.D., Tunkhannock Pa.

ANSWER—As in so many other things, a medium course seems the wiser and more feasible policy. Trying to train an infant to bladder and bowel control in the first few weeks of life is futile so far as the former is concerned. The latter commonly consists at that early age of using a suppository or a soap stick at regular times for a baby who normally has only one or two stools a day. This can hardly be called habit control. Control of the bowels is, however, quite possible and desirable for obvious reasons, perhaps in the majority of instances beginning around the third or fourth month. The use of a suppository, or soap stick until a conditional reflex is established, is a justifiable and efficient method of establishing the habit at that age but, of course, must not be kept up indefinitely. Bladder control is a far more difficult thing to establish. There is "no danger, if any" in starting earlier, but success is rarely attained before the end of the first year, and only too frequently not for a long time after that. It is worth trying, however, somewhere between the middle and the end of the first year. Babies vary greatly in this respect, and some individualization is desirable. At best, "house breaking" is not as simple and easy in the baby as it is in the dog.

MUSCULAR OR NEURITIC DISTURBANCE

To the Editor—I have an unusual case on hand of neuritis of the sensory nerves involving the upper and lower extremities, the abdominal and chest muscles, the pectoral and intercostals and the fifth and eighth nerves. Pain, stiffness and a constriction like feeling of the muscles are the common symptoms of each nerve section involved. There is no loss of reflexes or tactile sense. Deep muscular sense is altered. There is no paralysis but the patient is confined in bed because of severe fatigue and myasthenia. The cranial nerves were involved last although head ache and pain in the cervical region occurred early. Blood counts, chemical examinations of the urine and the temperature remain normal. The case is of nine weeks standing. Have you any information of such cases? Have any been reported in the literature? Any information as to the etiology and treatment will be appreciated or any suggestion that may be of help in clearing up this case.

M.D. New York.

ANSWER—The symptoms indicated do not suggest the diagnosis of a neuritis, and there is no possibility of making a diagnosis on the basis of the observations reported. It is possible that the primary disturbance is muscular rather than nervous.

DRIBBLING AFTER URINATION

To the Editor—A patient is troubled by the persistent dribbling of a few drops of urine after voluntary micturition is finished. The amount is small, just enough to stain the underclothing but is annoying to the patient and cannot be controlled. The urine is normal as is the urinary tract except for a history of an acute nonspecific prostatitis about five years ago. Kindly omit name.

M.D. Maryland

ANSWER—If the patient is old enough to have hyperplastic changes in the prostate gland, this may be the cause of the dribbling. Early in the course of prostatic hypertrophy the enlarging gland interferes with the sphincteric action, resulting in dribbling.

Disturbed innervation to the bladder from a cord lesion may also cause dribbling. The cause of the dribbling should be investigated both by cystoscopic examination and by a neurologic study.

RHEUMATIC NODULES IN RHEUMATIC FEVER

To the Editor—A child aged 11 years has been confined to bed for nine weeks with acute rheumatic fever involving all the large joints and including the ribs. Heberden nodes have developed along the occipito-parietal suture. The child is suffering also from a mitral regurgitation from a previous attack. I should like to know whether these nodes have any relation to the rheumatic fever. I should also like to know whether you have heard of any cases similar to this.

NATHAN STEINBERG M.D. Philadelphia

ANSWER—Heberden nodes are small, bony outgrowths occurring on the joint of the terminal phalanges. They are associated with hypertrophic osteo-arthritis and may be the first or the only manifestation.

The nodes described in the query are rheumatic nodules and are a frequent manifestation in rheumatic fever. They occur most typically at the tendinous insertions of the muscles, and the region described is one of the regions where they are most likely to be found. Next in order of frequency would probably be close to the wrist or elbow or the knees, but they may be found over the shoulder or hip or shoulder blades, and much less frequently elsewhere. They are a manifestation of rheumatic fever just as is arthritis, chorea or carditis. They should always be looked for in doubtful cases, in which they may be the determining manifestations.

CARCINOMA OF LARYNX

To the Editor—Some very interesting figures and comments are made regarding carcinoma of the larynx in *Recent Advances in Radium* by Ward and Smith, published in 1933 by P. Blakiston's Son and Company (pages 197-201). Contard's results using x-rays alone (21 per cent of eight year arrested cases) speaks favorably for irradiation (p. 200) while surgery though results are equally good gives a lesser degree of conservation of function and a varying operative mortality which averages about 15 per cent. See also *Treatment of Cancer of the Larynx* K. Amersbach and L. Krause *M. Klin.* March 9 1934.

The question of the form of therapy giving the best results is not settled but it is my opinion that the following is as near the truth as we know it at the present time.

A. Intrinsic carcinoma with involvement of the vocal cords alone can be treated by either surgery or irradiation and the efficacy will be more dependent on the experience of the surgeon or radiologist than on the type of treatment. With irradiation there is a better conservation of the voice with surgery the technical procedures have been established longer. Possibly the solution will be a combination of surgery and irradiation. At present most workers are in favor of surgical treatment because of the following.

There is little difference recorded as yet between the results over comparable periods because surgery has been long accepted as the method of treatment most workers are surgeons. The last part of the foregoing statement is not meant to imply that the eminent laryngologists are biased but rather that it is only natural to view the stars through one's own telescope.

B. For lesions more advanced, i.e. with involvement of cartilage or glands the treatment is palliative at the present time. Therapy should be either surgery plus radium (Hamer's method) or external irradiation.

HAROLD A. HILL M.D., San Francisco

MAPHARSEN AND SYPHILIS

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* July 18 page 232 headed Mapharsen and Syphilis a question dealt with the treatment of a carpenter aged 42 with secondary syphilis. After fourteen injections of mapharsen and ten injections of insoluble bismuth the patient was found to have a partially positive spinal fluid formula. It showed a two plus Wassermann reaction and a partially positive first zone colloidal gold curve. This has the appearance of a spinal fluid picture which is returning to normal and not that of fulminating nervous system involvement.

Tryparsamide was recommended in alternation with a heavy metal. Since an appreciable percentage of patients with secondary syphilis have positive spinal fluids and since in the majority of these patients spinal fluids become negative under a standard course of treatment of neocarsphenamine and a heavy metal I think that routine treatment should at least have been mentioned in the answer. Only two arsenicals were discussed. One was mapharsen the newest arsenical used in the treatment of syphilis which has not been completely appraised. The other was tryparsamide a quinquivalent arsenical its usefulness limited to central nervous system syphilis. The method of choice it seems to me in this patient would be an intensive standard course of treatment with one of the proved arsphenamines namely neocarsphenamine or arsphenamine in alternation with a heavy metal for a reasonable period before considering a very new or a highly specialized drug for the treatment of a very usual clinical variety of syphilis.

The answer satisfactorily covered the uses and limitations of mapharsen. It seems to have omitted however the standard treatment course as outlined by recent study of the Cooperative Clinic Group.

ARTHUR G. SNOOK M.D. Dallas Texas

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, June 6, 1936

Hospitals Approved for Intern Training

St. Luke's Hospital, Jacksonville Fla
Jennie Edmundson Memorial Hospital Council Bluffs Iowa
St. Joseph's Mercy Hospital Detroit
St. Mary's Infirmary St. Louis
St. Mary's Hospital Orange N J
Aultman Hospital Canton Ohio
Frankford Hospital Philadelphia

Book Notices

Administration of Workmen's Compensation By Walter F. Dodd
Cloth Price \$4.50 Pp 845 New York Commonwealth Fund London Oxford University Press 1936

Ever since the enactment of the first workmen's compensation law in the United States, there have been almost continuous changes in the state statutes, commission regulations and methods of administration. All who are interested in workmen's compensation and in the problems of governmental administration will find this study helpful not only in its discussion of the many intricate problems involved but also in its presentation of those methods of administration which have proved most satisfactory. The author first presents a historical sketch in which he discusses the common law liability defenses as developed by the courts prior to the adoption of workmen's compensation laws. These common law defenses are the fellow servant doctrine, the assumption of risk, and contributory negligence. Insufficient compensation for the injured workmen, wastefulness of the system, delay, and antagonism between employer and employee are some of the conditions of the liability system which commissions and individuals sought to ameliorate in their search for a new remedy. This remedy was found in a form of insurance copied largely from English law and experience. The amount of discussion devoted to the various methods of administration of the workmen's compensation acts in the United States is an indication of the proportions to which the system has grown as an insurance business.

The primary objective in the early administration of workmen's compensation was to provide relief to employees while recovering from injuries. Medical care was largely incidental and not utilized to the best advantage in shortening the period of disability. Over the last twenty-five years the change in attitude toward the importance of medical care under workmen's compensation is in many instances striking. The author presents fairly the points of view of interested parties on medical problems that have demanded attention. Those who hope to find in this work of defense or encouragement of some of the unfair methods of providing medical care will be disappointed.

The compensation statutes, which with few exceptions make the employer, which means the insurer, responsible for paying medical benefits, have given these parties a financial interest in keeping medical costs as low as possible. This is done in most cases by the control of the employee's physician. The worst feature of this commercialization of medical practice by delivering bargaining power into the hands of a few has been the exploitation of the health of the employee.

The author recommends that all insurance and commercial clinics and hospital associations or other organizations which operate to treat industrial injury cases for profit should be abolished by law, and that the treatment of all compensation cases, except for first aid, should be confined exclusively to a panel of physicians nominated by the officers or a committee of the county medical society. He adheres to the principle that the employee should be given considerable voice in the selection of his own physician, thus encouraging the patient's confidence in the physician, an essential element in recovery. In other parts of this work there are discussions on types of insurance, regulation of insurance carriers, noninsurers measures of compensation, workmen's compensation and accident prevention, lump sum settlements, noncompensable industrial injuries, administrative organization, and the progress of workmen's compensation.

The author expresses the opinion that 'Much remains to be done toward bettering the content and administration of compensation laws. This need should not be lost sight of because of present movements for unemployment, old age and health insurance including insurance for injuries that are not industrial. Workmen's compensation may be affected by these institutions, if they are adopted, but the compensation plan in its administration and in its actuarial basis must be kept separate if the cost of compensation is to continue as an expense charged to industry with respect to accidents and diseases attributable to the industry. The charge to industry of the cost of workmen's compensation should not be united with other types of social insurance. Workmen's compensation should be an obligation of industry, other types of social insurance if undertaken, should be an obligation of society, of which industry is but a part.'

This work is timely and illuminating in many phases of workmen's compensation administration. In a study that appears to have been so carefully done, it is to be regretted that the author did not include some discussion of the efforts being made by cultists and irregular practitioners to establish themselves on an equal basis with the medical profession in the treatment of compensable injuries. In general this book will be welcome and valuable assistance to all who are interested in improving the administration of workmen's compensation in the United States.

Manual of Emergencies Medical Surgical and Obstetric Their Pathology Diagnosis and Treatment. By J. Snowman M.D. M.R.C.P. Third edition. Fabrikoid. Price 10s. Pp 401. London John Bale Sons & Danielsson Ltd 1936.

This little book has made an excellent impression. Packed within its covers is a wealth of sensible information and advice concerning the most urgent situations in medical and surgical practice. The general plan is to consider each condition under the headings of pathology and physiology, symptoms, diagnosis, prognosis and treatment. A wide field is covered. The first section deals with the dangerous emergencies in diseases of the respiratory system and includes hemorrhages, spasmodic laryngitis, spasm of the glottis, edema of the larynx, asthma, foreign bodies and injuries to the trachea, acute pulmonary edema, massive collapse of the lung, and pneumothorax. The second section deals with the emergencies of heart disease such as cardiac dyspnea, auricular fibrillation, anginal attacks, pericardial effusion and heart wounds. The common causes of sudden loss of consciousness and of convulsions are discussed. The short section dealing with intestinal obstruction, intussusception, strangulated hernia, acute pancreatitis and abdominal injuries adequately point out the more common danger signals. Twenty-four pages is devoted to emergencies occurring in connection with diseases of the urinary organs. The section on the various poisons is full and valuable. Seventy pages is devoted to the dangerous obstetric emergencies including the hemorrhages of pregnancy, extra-uterine gestation, rupture of the uterus and eclampsia. This book is valuable to read in anticipation of emergencies, when they occur it will be a comfort to have it at hand.

Skaz y lyudni patologichna anatomii klinika patogenez patofiziologii [By] N. M. Krol. Le rage chez l'homme. Anatomie pathologique clinique pathogénèse et pathophysiologie. Paper. Price 7 krb. Pp 355 with 33 illustrations. L'kharkov Derzhmedvidar 1936.

This contribution from the Ukrainian Psychoneurologic Academy is based on a study of seventy-five clinical cases of rabies, in seventeen of which a histopathologic study was made. Eight of the latter group were studied by the method of serial sections of the entire cerebrospinal axis. The lesions were focal in character and were found at all levels. Two predominant groups were separated, the inflammatory and the degenerative. In some cases the glial proliferation resembled that of a postvaccination encephalitis and suggested the possible influence of antirabic inoculations. The author disagrees with K. Schaffer, who maintained that most pronounced inflammatory changes were found in the spinal cord segment corresponding to the level of the initial lesion (bite). The alterations of the glial cells were of the grave type described by Nissl. The author disagrees with the opinion of H. Pette and gives support to the view of Spielmeyer that there is nothing characteristic or pathognomonic about the alterations in rabies which would enable one to distinguish it from the various types of epidemic encephalitis. Thus, he believes, his observations substantiate one of the fundamental concepts of the general theory of infections of the nervous system, namely, the variability of alterations developing under the influence of the same infectious virus. His studies demonstrate the impossibility of differentiating on the histologic alterations alone between the rabies of the inflammatory type of reactions and the various types of epidemic encephalitis. The differentiation can be made on a combined clinical and histologic study, the finding of the Negri bodies and animal inoculations. The author makes an interesting attempt to correlate the clinical symptoms with pathologic alterations. He relates the complex of symptoms, which he designates as 'sympathetic tempest' with the lesions of hypothalamus. While admitting the importance of Bonhoeffer's concept of nonspecificity of psychic reactions in infectious

psychoses, he believes that the brain may react in a specific manner in response to a particular infection. An extensive bibliography and a chart of differential histologic diagnosis of acute nonsuppurative infections of the central nervous system are appended.

The Chemistry of Natural Products Related to Phenanthrene. By L. F. Fieser. Associate Professor of Chemistry, Harvard University. Cloth. Price \$6.50. Pp. 358. New York: Reinhold Publishing Corporation, 1936.

The developments during the past few years in the chemistry and physiology of the sterols constitute one of the most fascinating stories in biologic and chemical research. Newly isolated sterols have provided the keys to many puzzling problems in physiology, pharmacology and therapeutics, but even this tremendously rapid growth represents only a small step in the much wider elucidation of fundamental biologic phenomena which the near future promises. Because the subject is relatively new and because its development has been so rapid, a comprehensive and critical evaluation of this field has become urgently necessary. This need has now been ably supplied by Professor Fieser with an unusually well written book. The author has reviewed the literature to Feb. 1, 1936, thus this volume contains all but the most recent contributions. The subjects covered include the chemistry of phenanthrenes, resin acids, cancer-producing hydrocarbons, sterols and bile acids, sex hormones, heart poisons and saponins. The text is replete with structural formulas. Data are presented on methods of extraction of naturally occurring products, on methods of synthesis (or "pseudo-synthesis") of these and related compounds and on their physiologic effects, so far as the latter are known. The elucidation of the chemical structure of these substances is considered at length. The bibliography is extensive. The author is to be congratulated on a beautifully concise and lucid presentation of a very difficult subject. This book will be an indispensable acquisition to the library of all those interested in this fundamental field.

Gefässmissbildungen und Gefässgeschwülste des Gehirns. Von Prof. Dr. Eilund Bergstrand, Direktor des Instituts für allgemeine Pathologie und pathologische Anatomie des Karolinschen Instituts in Stockholm. Prof. Dr. Herbert Olivecrona, Direktor der neurochirurgischen Klinik in Stockholm, und Prof. Dr. Wilhelm Tönnis, Leiter der neurochirurgischen Abteilung des staatlichen Luitpoldkrankenhauses in Würzburg. Paper. Price 24 marks. Pp. 181, with 137 illustrations. Leipzig: Georg Thieme, 1936.

This work is another of the excellent series of monographs on neurosurgical subjects that have appeared from the Neurosurgical Clinics in Stockholm. In the present instance Professor Bergstrand of the Institute for General Pathology and Pathologic Anatomy, Stockholm, and Professor Tönnis of Würzburg have collaborated with Professor Olivecrona. The monograph presents in clear form the authors' experience in a large series of cases of vascular neoplasms and malformations, as well as a comprehensive review of the relevant literature. The authors have classified these lesions as follows:

1. Angioma cavernosum.
2. Angioma racemosum.
 - (a) Telangiectasis.
 - (b) Sturge-Weber's disease.
 - (c) Angioma racemosum arteriale.
 - (d) Angioma racemosum venosum.
 - (e) Aneurysma arteriovenosum.
3. Angioidculoma (hemangioblastoma of Cushing and Bailey, or Lindau's disease).
4. Angioglioma (of Roussy and Oberling).

The pathologic anatomy, symptomatology and treatment of each is discussed. The monograph is well illustrated. There is an extensive and comprehensive bibliography.

Experimentelle Undersøgelser over en transplantabel Leukose hos hvide Mus. Af B. C. Rask-Nielsen. [Experimental Studies on Transplantable Leukosis in White Mice]. With an English summary. Paper. Price 12 kronor. Pp. 159, with 39 illustrations. Copenhagen: Levin & Munksgaard, 1936.

This doctorate thesis deals with the details of experiments on a transmissible leukosis in white mice, starting in a spontaneous instance. Successful transmission was obtained by subcutaneous or intravenous injection of leukosis cells in mice after roentgenization or injection of trypan blue. The peculiar cells were round and of varying size, a narrow rim of basophilic non-granular cytoplasm enclosing a round or curved nucleus with

a fine chromatin network and from two to five nuclei. These cells occurred in varying numbers in the blood as well as in local growths and infiltrations, there also developed myeloid hyperplasia in the marrow and spleen. Comparing this instance with previously described forms of transmissible mammalian leukosis, it appears that Korteweg observed a similar variety in 1929. These two instances are peculiar mainly in that a sudden neutrophil leukocytosis developed before the appearance in the blood of the characteristic cells. As in other forms, the disease in the present case depended on the proliferation of malignant cells, which the author suggests may have been immature and pathologic myeloblasts.

L'immunité au cours de la tuberculose. Etude expérimentale et clinique. Par Jean Paraf. Préface du Professeur F. Bezançon. Bibliothèque de phthisiologie sous la direction de Léon Bernard. Paper. Price 30 francs. Pp. 141. Paris: Masson & Cie, 1936.

This book, which is a new monograph in the well known "Bibliothèque de phthisiologie," founded by Léon Bernard, is a brief but interesting exposition, the central theme of which appears to be rationalization of BCG vaccination on the basis of immunology, and removal of the method from the field of empiricism. As such it is worth the attention of all physicians interested in this subject. An important role in immunity is ascribed to allergy, which, in the words of the author and Jules Bordet, if not part of immunity at least comes to its assistance. In Paraf's experience the most resistant infants and animals vaccinated with BCG are those in which a mild superinfection with virulent bacilli from without has increased the degree of allergy. Tuberculin treatment and the therapeutic use of BCG are discussed in the light of their relation to allergy.

Prostitution in the Modern World. A Survey and a Challenge. By Gladys Mary Hall, M.A. With an introduction by Charles E. Parnes, D.D., Regius Professor of Divinity, Cambridge. Cloth. Price \$2. Pp. 200. New York: Emerson Books Inc., 1936.

This volume stresses the great changes in the problem of prostitution resulting from the effects of the great war. The most significant change, the increase in the noncommercial form of promiscuous sex relationships, leads the author to define prostitution "to include paid and unpaid forms of sex promiscuity," a definition at marked variance with almost all other writers, who make barter an essential element in prostitution. Except for Great Britain, only fragmentary data are presented on the extent and practice of prostitution and the nature and effectiveness of legislation on prostitution in the chief countries of the world. The conclusion is reached that commercialized prostitution is decreasing and that unpaid promiscuity is increasing in nearly all the countries of the world. In the United States both forms of promiscuity are reported to have increased. The data presented, however, are insufficient to show the increase of commercial prostitution in this country and no reference is made to Vice in Chicago by W. C. Reckless, with its detailed statistics on this point for one American city. Important factors in prostitution, according to the author, are in women (1) desire for luxuries rather than economic need, (2) housing and neighborhood conditions due to poverty, (3) loneliness, monotony or other work conditions, (4) alcohol, (5) assault in childhood, (6) knowledge of contraceptives, (7) mental defect in a smaller proportion of cases than generally supposed, (8) temperament, (9) desire for sex experience, and in men (1) a social belief in the masculine need for sex relations, (2) curiosity and adventurousness of youth, (3) marital maladjustment and (4) demand for sex relations as an important individual experience. Two chapters are devoted to traffic in women and children and to the results of sexual promiscuity and abstinence. The final chapter is a challenging reply to the new morality which consists 'in the view that temporary unpaid sex relations outside marriage are not merely permissible but desirable not only as preparation for marriage or without prospect of marriage but during marriage itself and with the knowledge and acquiescence of the marriage partner.' The author's conclusion that the need on occasion for a deliberate canalizing of the creative energy in the direction of other than sexual purposes 'is a statement of her own convictions rather than a generalization from her data. Although the volume contains useful comparative data, it falls far short of an adequate treatment of its subject. Its defects are chiefly due to the unwarranted extension of the term prostitu-

tution to include all sexual promiscuity and to the difficulties inherent in an attempt to make a world-wide survey of the problem in the absence of scientific studies in the different countries

Undersøgelse over en Gruppe Actinomyces Isolerede fra menneskets svamp Af Rigmor v. Magnus [Studies on a Group of Actinomyces Isolated from Human Pharynx] With an English summary Paper Price 6 kroner Pp 132 with 4 illustrations Copenhagen Levin & Munksgaard 1936

In 1923 Orskov demonstrated the presence of branching organisms in the human pharynx. This discovery depended mainly on direct microscopic observation of growing cultures on agar, in making smears in the usual way the branchings are easily broken up. The present report, which is a thesis for the doctor's degree, presents the results of an extensive study of this group of organisms, 130 strains of which were isolated from the pharynx and nasopharynx. The culture and other characteristics of the organisms, which appear to be non-pathogenic, are described. An interesting observation is that most of the strains, especially those belonging to the acid group, produce the enzyme which by its action on human red blood corpuscles renders them agglutinable to human serum in general, including the serum of the person whose corpuscles are examined (the so-called T agglutination described by Thomsen)

The Medical Formulary and Prescription Manual. A Treatise on Prescriptions and Prescription Writing. By Morris Dauer Ph.G. Chief Pharmacist at Kings County Hospital Borough of Brooklyn City of New York. Approved and adopted by the Department of Hospitals City of New York September 13 1934. Fabrikoid Pp 297 Brooklyn N.Y. The Author 1935

This little volume contains a great deal of valuable information on the prescription and compounding of medicinal agents. It includes, in addition to descriptive material and tables of various kinds, 957 separate preparations. Even allowing for duplication in different dosage forms of the same drug, the number of remedies in this formulary surely exceeds the necessities of rational therapeutics. Many irrational mixtures are included, the section on glandular preparations, which contains such preparations as "Tablet of Pineal Gland" and "Tablet of Suprarenal Gland," is particularly objectionable. It is not clear why almost the whole range of therapeutic substances should be covered separately as "Diabetic Medicinal Preparations." The prescriptions are numbered consecutively throughout the book, this leads readily to prescribing by number, a hazardous practice which has caused many accidents. It is hoped that in future revisions of this volume the objectionable features will be eliminated (the author might with benefit consult N. N. R. and Useful Drugs). Much of the material is excellent and it is unfortunate that a book otherwise so useful should contain so much irrational material. The printing and binding are unusually well done.

Die Porphyrine. Ihr Nachweis, ihre Physiologie und Klinik. Von Dr. med. habil. Curt Carrière Assistent an der Hautklinik der Medizinischen Akademie in Düsseldorf. Boards. Price 9 marks Pp 103 with 34 illustrations Leipzig Georg Thieme 1936

This is an interesting review of the significance of the porphyrins in biology and clinical medicine. The porphyrins are chemically closely related to the other blood pigments (hemin, bile pigment) and to chlorophyll. The chemistry of the porphyrins is discussed from the medical standpoint. Blood pigment, porphyrins and chlorophyll are composed of four heterocyclic pyrrole rings, to which methyl and ethyl groups are attached. The chemical formulas of the more important compounds are described. Then the qualitative and quantitative methods of isolation are given. The biologic properties of the porphyrins are numerous. The best known is their photosensitizing action. These substances have a special affinity for the skeletal system. Porphyrins have been found normally in the red blood cells, urine, bone marrow and other structures. Porphyrins are increased in the urine in various febrile diseases that lead to red blood cell destruction, also after arsenic medication and in malaria, pernicious anemia and hemolytic icterus. Liver cell destruction also causes an increased excretion. The clinical forms of porphyrinuria, acute, congenital and toxic, are described. The porphyrinopathies are divided into (1) primary and (2) secondary. There is a bibliography of 252 references and an index.

Les encéphalites aiguës post infectieuses de l'enfance. Par Marié Thérèse Comby. Préface du Dr J. Comby. Paper. Price 30 francs Pp 172 with 6 illustrations Paris Masson & Cie 1935

The term "encephalitis" has come into general use only since the great epidemic swept the world in 1917-1919. Prior to that time acute encephalitis was not recognized except for those types due to syphilis, trauma or sepsis. Many cases caused by other agents, presumably the filtrable viruses, have now come to light. This volume gives the reports on forty-five patients, all children, showing a wide variety of symptoms and signs pointing to a diffuse lesion in the brain. Epidemic (lethargic) encephalitis is excluded. The group is diffuse. Some cases followed vaccination, others followed chickenpox, measles, scarlet fever, diphtheria and other childhood diseases. Others appeared without preceding disease. The presentation of such a wide variety of material, without more complete classification, only leads to confusion. Although the bibliography is somewhat useful, the book itself cannot be highly recommended.

A Third Index of Patented Mothproofing Materials. By R. C. Roark and R. L. Busbey. Division of Insecticide Investigations. Bureau of Entomology and Plant Quarantine. United States Department of Agriculture. Washington D. C. Paper. Pp 104. Washington D. C. 1936

This volume is just what its title indicates it is. Patent numbers are given and the patents briefly described. Toxicities and allergic reactions are not mentioned.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance. Streptococcal Infection or Staphylococcal Infection as Cause of Death.—The defendant insurance company agreed to pay certain benefits if the death of the insured resulted "directly and independently of all other causes from bodily injury effected solely through external, violent and accidental cause." These benefits were not to be payable if the death resulted from "physical or mental infirmity, or directly or indirectly from illness or disease of any kind." The insured slipped on the back steps of his house and fell, sliding down several steps. A boil that he had on his right arm was found to be broken and bleeding after the fall, but the insured appeared to be in good physical condition and made no complaint of being in pain. On the night of the day following the fall, however, he was restless and suffered pain in the region of his left buttock. The following morning he walked with a limp, dragging his left leg. A painful red area about the size of the palm of the hand developed on his left buttock and he was forced to go to bed. At times his temperature was normal and at other times he had alternate periods of sweating and fever and chills. He grew worse during the next few days and continually indicated the pain in his left buttock as the cause of his suffering. On the third and fourth days after the fall, swelling set in about the insured's knees. He died on the seventh day after the fall from "septicemia, septic pneumonia, and septic arthritis." The beneficiary obtained judgment in the trial court and the insurance company sought a reversal of that judgment in the Supreme Judicial Court of Massachusetts.

The defendant contended that staphylococci, coming from the boils from which the insured suffered periodically during his lifetime, caused the death and that the causation was not affected by the fall. The beneficiary argued, on the other hand, that the fall activated otherwise harmless streptococci present in the body of the insured. Two physicians, testifying for the beneficiary, in answer to hypothetical questions, stated that the fall caused lowered resistance of tissues in the region of the left buttock, activating streptococci, which in a harmless form are present in every one, and that the infection spread through the blood stream to the insured's knees, developing into septic arthritis. These witnesses admitted that the septicemia might have been brought about by staphylococci from the boils, as was contended by the medical witnesses for the

insurance company, but testified that the symptoms were more properly referable to a conclusion of streptococcal infection. The alternately high and low temperatures and involvements of the joints, as well as other symptoms, were typical of streptococcal infection and not consistent with staphylococcal infection, which, if it had started from boils, would have become active sooner than it did. Staphylococcal infection, the witnesses continued, is marked by a uniformly high temperature with no long swings from one extreme to the other.

The testimony for the beneficiary, the court concluded, was sufficient to justify a submission of the question to the jury, and the court could find no reason to disturb the judgment for the beneficiary.—*Kramer v New York Life Ins Co (Mass)*, 200 N E 390

Health Departments Records as Public Documents—The appellant, Dr P E Marks, was the superintendent of the bureau of infectious diseases of the city of Pittsburgh. In connection with a pending suit by a beneficiary against an insurance company, Dr Marks was served with a subpoena requiring him to produce the records of his bureau relative to the insured, showing when the insured was reported to the bureau as being tuberculous. Dr Marks appeared in court pursuant to the subpoena but, on the advice of the city solicitor, refused to produce the records on the ground that it would be against public policy so to do. The court adjudged the witness to be in contempt of court. Thereupon Dr Marks appealed to the superior court of Pennsylvania.

There is, said the court, no express statutory provision that the data compiled by the department of health shall constitute public records, except in a very few instances, and the expression of these few instances implies the exclusion of the rest. An examination of the statutes relating to the department of health shows two broad general aims and purposes in view: (1) the collection of vital statistics, such as births, deaths and marriages, (2) the preservation of the public health and the prevention of disease. Data under the first class are gathered for public use and inspection, and the statutes requiring them to be furnished provide that official certificates of the statistics so furnished shall be given to the public on the payment of a small fee. These are public documents, receivable in evidence as an exception to the hearsay rule. But information gathered or received for the preservation of the public health and the prevention of disease is not always and in all cases designed or intended for inspection by the public. It may be contrary to the public interest to allow it to be made public. In the absence of statutory pronouncement on this subject, the officer in charge must be allowed to decide what information so received is proper for publication or general inspection and what should be withheld in the public interest. The court expressed itself as in agreement with the statement made by the assistant city solicitor, who presented this case on appeal, as follows:

These records are in no true sense of the words "public records" they are departmental records. To thwart the important functions of the Health Department by placing their confidential data in the hands of the general public would effectively impair the important work performed by this Department in the prevention, control and treatment of infectious diseases. It is earnestly submitted that the interests of the public in protecting itself and those afflicted with dangerous infectious diseases far outweighs any benefit that insurance companies or other litigants might gain by reason of ready access to departmental records.

The judgment of the trial court, adjudging the witness in contempt, was therefore reversed.—*In re Marks (Pa)* 183 A 432

Malpractice Liability of Anesthetist for Injury to Patient's Eyes Due to Ether—The plaintiff underwent an operation for the removal of a thyroid cyst. The defendant, a physician, was engaged to administer the anesthetic. He was assisted by a nurse provided by the hospital. Alleging that the defendant negligently administered the ether, resulting in serious injury to her eyes, the plaintiff sued the defendant. At the close of the evidence a motion by the defendant for a directed verdict was denied. A verdict was rendered for the plaintiff and the defendant appealed to the Supreme Judicial Court of Massachusetts.

There is no evidence, said the Supreme Judicial Court, that the defendant did not possess the standard of skill which the law requires him to possess, nor is there any testimony in the record that the defendant departed from the usual technique in handling the anesthetic. The fact, warranted by the evidence, that the plaintiff's eyes were injured by the administration of ether by the defendant does not alone warrant the inference of fault on the part of the defendant. In the absence of expert affirmative evidence of fault in the administration of ether the basic question is whether the defendant in administering the ether did use the care and skill which the law requires. There is nothing in the record to exclude the reasonable inference, the court said, that the nurse in pouring the liquid ether spilled it on the outside of the cone and that it found its way to the plaintiff's eyes to their harm. If such was the fact the defendant was not responsible. The nurse was furnished by the hospital and there is no evidence that the defendant directed or failed to direct her other than to say that the liquid ether she poured into the cone was "enough." In the opinion of the court, the trial court should have directed a verdict for the defendant. The Supreme Judicial Court, therefore, entered judgment for the defendant.—*Alucken v Linn (Mass)*, 200 N E 566

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Rheumatic Fever and Coronary Artery Disease and Thrombosis.—Gross and Oppenheimer studied the postmortem material of 3,264 cases, in which they found thirty instances of coronary arteriosclerosis concomitant with rheumatic valvular disease. They believe that the association may have been purely coincidental. Either the valvular or the vascular lesion predominated and apparently was responsible for the clinical picture observed during life. There was no proved etiologic relationship between the initial valvular lesion and the subsequent development of coronary arteriosclerosis. The two lesions may be independent and unrelated. If a causal relationship did exist, coronary arteriosclerosis would occur with greater frequency at an earlier age in patients with rheumatic heart disease. The coronary arteries of young patients with rheumatic heart disease are usually free of arteriosclerotic changes. Despite the rather frequent involvement of the coronary arteries during the course of acute rheumatic fever it has not been possible to establish such an entity on clinical grounds. To diagnose coronary disease from the electrocardiogram is unsafe. Published electrocardiograms indicating such relationship are equivocal, since similar changes may appear during acute rheumatic fever, aortic insufficiency pericarditis or coma. Though the association of rheumatic valvular disease and coronary sclerosis is a rarity and the diagnosis is difficult, it has seemed to the authors that in some cases such a diagnosis might be suspected. In an individual with signs and symptoms of rheumatic heart disease who survives middle life and later develops anginal pain not attributable to aortic disease active rheumatic fever or pericarditis the coexistence of coronary disease is to be suspected. Rare cases of angina pectoris in mitral stenosis without evidence of active rheumatic fever occur. In the absence of aortic insufficiency, an electrocardiogram may be of great help. The greatest and most significant reason for the very infrequent association of rheumatic and coronary disease is that rheumatic fever appears early in life and ordinarily runs its course before the usual period of degenerative heart disease. In several instances of severe coronary sclerosis the associated rheumatic valvular lesions were insignificant and

such as are frequently found at necropsy of persons dying of other diseases. Similarly, in several cases of advanced rheumatic valvular disease the coincidental arteriosclerotic lesions of the coronary arteries were of no significance. In still others neither the vascular nor the valvular lesion was of more than pathologic interest, and the patient had presented neither history nor symptoms indicative of rheumatic heart disease or coronary arteriosclerosis. Cases may be cited of rheumatic subjects at or beyond middle life in whom coronary disease corresponds roughly to the age of the individual.

Intermittent Venous Compression in Treatment of Peripheral Vascular Disease.—Collens and Wilensky endeavored to incorporate the beneficial effects of venous obstruction and release in the treatment of peripheral vascular disease by utilizing an apparatus designed to produce alternating periods of venous congestion and release of congestion. Sustained venous compression at from 30 to 60 mm of mercury for two minutes followed by a release of this pressure for another two minutes resulted in clinical benefits. The technic consisted of applying venous compression at the mid thigh alternating with release in periods of two minutes for as long as twelve hours continuously each day. The criteria employed in determining the effectiveness of treatment consisted of (1) a walking test, (2) a hot water immersion test (Landis), (3) oscillometric readings, (4) relief of pain, (5) healing of ulcers and (6) effect of treatment on skin temperature. Following treatment there was relief of pain, increase of skin temperature of the extremity, increase in walking efficiency, increase in vascularity (permitting amputation at lower levels) and healing of chronic indolent ulcers associated with vascular obstruction.

Chemotherapy Investigations in Cancer.—Woodhouse concludes from his experiments that not one of the lead compounds investigated was a suitable agent for controlling frankly malignant growths. It is possible that in those cases in which the lead injections caused inhibition of growth the epitheliomas were less active than usual. This is in keeping with the conclusion of Eggers who found that some hexose-lead compounds were able to cause rat tumors of low virulence to disappear but had no influence on the more malignant sarcoma 39. In the authors' experience true epitheliomas produced by tar in mice are very lethal although the percentage of metastases is not high. He finds, therefore, that even compounds such as

benzene-sulfonyl-glycine, which are able to oppose grafted tumors with a good measure of success, do not appreciably inhibit the more "virulent" strain of neoplasm. It is felt, however, that the type of tumor utilized in the investigation is more closely allied to spontaneous cancer, and, if experiment should devise a nontoxic substance capable of destroying this form of growth, the greater part of human cancers would come within its sphere of attack.

Multiple Primary Cancers—Because multiple primary cancers have been found to occur oftener than expected among necropsy cases at the State of Wisconsin General Hospital, Burke tabulates such cases and computes their incidence. In a period of eleven years ended in October 1935 2,889 deaths occurred and 2,033 necropsies were performed, 583 disclosed cancer, an incidence of 28.6 per cent, which approximates that found at Michigan and at the Mayo Clinic and apparently reflects a certain degree of selectivity in these institutions for cancer patients. There were forty-six cases of multiple primary cancers, representing an incidence of 7.8 per cent, thus far the highest to be reported in any series of cases, surgical (morbidity) or necropsy (mortality). Thirty-five of the cases occurred in males, eleven in females. However, the entire necropsy series discloses a 2:1 preponderance of males over females. The heredity factor was positive in fourteen cases, negative in twelve cases and incomplete or unelicited in twenty cases. Except in four cases the tumors were synchronous. In seven of the cases one of the tumors was a sarcoma. The commonest type of multiple cancer, the basal-cell epithelioma, was conspicuous for its rarity in the series (three instances). Besides the forty-six cases there was a miscellaneous collection of seventeen cases failing for one reason or another to satisfy fully the criteria for multiple malignant conditions. A cancer is defined as a definite, atypical, invasive growth, it is not mere local hyperplasia, in the absence of metastases it must show definite local invasive activity. Nine of these cases showed one true cancer and an atypical, invasive hyperplasia of the prostatic epithelium that had not yet reached the stage at which it could be considered a definite tumor. Two cases represented an analogous condition in which the bladder epithelium and a gastric myoma were exhibiting the invasive tendency. In one case there was one malignant tumor and an embryonic rest from Rathke's pocket in the proper site for a possible craniopharyngioma. In two cases there was one malignant growth and another tumor, benign histologically but fatal. There was one case each of embryonic carcinoma of the kidney pelvis with multiple papillomas of the larynx with recurrences after radium therapy, adenocarcinoma of the stomach with lymphosarcoma of mesenteric origin and fibrillar astrocytoma of the brain (cerebellum) in which a retinoscope revealed a tumor in the right eye, removal of which was not permitted at necropsy. The author's series shows a higher incidence of multiplicity, 7.8 per cent, than any thus far reported. Inclusion of any or all of the seventeen cases not satisfying the criteria for multiple growths would raise the figure to 10.8 per cent if all were included. Any factor producing an increase in single cancers is bound to produce at least a corresponding increase in multiple cancers, and as one consequence of this increase the notion of rarity formerly associated with this condition has vanished. It is not unlikely that in an appreciable number of cases now coming to necropsy because of cancer itself another true or incipient cancer would be found if complete and careful microscopic examination were the rule. Such examination of current necropsy material is apt to reveal not just an absolute but a relative increase in multiple cancers.

Errors in Interpretation of Cardiovascular Symptoms.

—White enumerates the twenty-eight conditions of pain mentioned by James Herrick that have been confused with coronary thrombosis. Dyspnea is often misinterpreted. The common breathlessness of neurocirculatory asthenia in a nervously tired person or in one who is "soft" and physically unfit has often been treated as cardiac dyspnea with restriction in exercise and with digitalis therapy when almost the opposite measures are indicated. Dyspnea of pulmonary origin is less commonly confused with cardiac dyspnea, but the error is made often enough to warrant much care in analysis. Chronic bronchitis with emphysema and weakness of the left ventricle with pulmonary vascular congestion and emphysema are the two conditions which in an elderly person, especially in the winter, are likely to be mistaken for each other. A chronic as well as an acute asthmatic state may be caused by congestion of the lungs secondary to heart disease. This is not widely appreciated. When there is marked mitral stenosis, the most common symptom is dyspnea on effort or in attacks (with or without asthma) or constantly. Such dyspnea is certainly to be ascribed to pulmonary vascular engorgement. But it is still the rule to attribute wrongly this dyspnea to heart, or rather myocardial, failure. To be sure, the dyspnea and pulmonary engorgement are due to the heart disease but they are not due to myocardial failure. Palpitation is due to the consciousness of forceful, rapid or irregular heart action. It is never in itself a sign of heart disease and should never be prognosed and treated as such until the patient has been carefully studied. It may imitate a cardiac neurosis or even neurocirculatory asthenia unless properly handled at the outset. The most common condition associated with palpitation is neurocirculatory asthenia, of which it is frequently the chief symptom. It is quite a common error for an overactive heart to be misjudged in size. The forceful apex impulse produces a widespread movement of the anterior chest wall, which may be seen and felt several centimeters beyond the cardiac apex itself. If the outermost point of this impulse vibration is taken as the left edge of the heart, and especially if the measurement is made following the curve of the chest rather than tangentially from the midsternal line a gross and misleading error results. It is a less common error to underestimate the size of the heart. On a few occasions it is possible to misjudge grossly the size of the heart on hasty examination when a fairly forceful impulse is felt near or in the midclavicular line in patients with mitral valve disease whose hearts are very large and whose powerful right ventricles may displace the anterior chest wall while the true apex impulse is in or near the left anterior axillary line. During a severe infection especially rheumatic fever that attacks the myocardium dilatation of the left ventricle may give rise to a mitral diastolic murmur (and in some cases even an accompanying thrill) which was thought pathognomonic of mitral stenosis in the absence of free aortic regurgitation producing the so-called Austin Flint murmur. The author believes that the murmur is due to the relative mitral stenosis (dilatation of left ventricular cavity and undeformed mitral valve), rather

there is any aortic regurgitation or not. Other diseases may cause temporary mitral diastolic murmurs as the result of left ventricular dilatation, this is especially the case in severe anemia due to any cause. When there is pulmonary vascular congestion in marked mitral stenosis, it is not primarily myocardial failure that is responsible but the mechanical influence of the valvular defect.

Electrocardiogram in Coronary Thrombosis—Feldman examined 108 electrocardiograms of patients with coronary thrombosis, paying particular attention to the changes in the initial ventricular complexes. Eleven tracings showed no changes in either the initial or the final ventricular complexes. Forty-five cases showed changes in the final ventricular complex (ST and T waves) only. Fifty-one records showed conspicuous Q waves in association with characteristic changes in the ST segments and T waves. Nineteen of these, belonging to the Q₁ group and almost always associated with the final ventricular deflection of the T₁ type, often displayed a conspicuous Q wave in lead I, while the other QRS deflections in this lead were small. Twenty tracings of the fifty-one were classified into the Q₂ group and were accompanied by the final ventricular deflection of the T₂ type. There were twelve curves showing Q₁T₂ only. In one case this was inconspicuous two days after the attack, only to become prominent three days later. Changes in the initial ventricular complex without accompanying changes in the final ventricular complex are rare in acute coronary thrombosis. Such a curve would speak, instead, for an old infarction. Most of the cases in which there were posterior infarctions showed tracings of the Q₂T₂ type, while the rest, either having multiple infarctions or a single posterior one, displayed curves that did not conform to either Q₁ or Q₂ groups. Other changes in the initial ventricular complex, such as marked reduction in amplitude or the development of intraventricular conduction disturbances, may occur in coronary thrombosis.

Prevention of Postauricular Fistula—McNichols states that of sixteen radical mastoid operations done in the last ten years in private practice, thirteen patients have dry epithelized

cavities, one died of meningitis after a primary skin graft and two were so unfortunate as to have moist ears with post-auricular fistula. One of these was an old scarlet fever ear and the other patient had diabetes. Both refused further surgical treatment. The operations were done as near as possible after the teachings of Kerrison with the facial canal well lowered. A Siebenmann flap was done on the ear canal, which, according to Rae, is the best. Following a study of the literature, a flap was sought that would permit closure of post-auricular wounds, provide wide opening for drainage through the external auditory canal and encourage growth of the epithelial covering. To cover and fill the mastoid cavity and tip, the adjacent periosteum, together with a fatty subcutaneous tissue, was chosen. A typical postauricular incision for the radical operation is made, and then at the upper tip of this incision a new incision is made at the right angles, upward and backward, for a distance of about 2 inches, dividing all tissues down to the bone. This flap is elevated, the anterior flaps are elevated and pushed forward, and the membranocartilaginous meatus is completely separated from the posterior wall of the bony meatus. After the mastoidectomy has been completed, the margins are beveled carefully. The skin of the anterior flap is now dissected from the subcutaneous tissue and periosteum. This dissection is carried down into the membranous canal. A thin bladed knife is now introduced into the membranocartilaginous canal and, hugging the floor, an incision is made outward until it bisects the incision from behind. The flap is used to form the roof, so there is no obstructing ledge below to interfere with free drainage. The periosteum and subcutaneous tissue are freed from the skin in the posterior flap. The under flap is freed from above downward to a distance of about 1½ inches behind the primary incision. This allows the graft to be moved forward and sutured by interrupted chromic sutures to the periosteal and fat graft from the anterior flap. Great care is taken to tie all bleeding vessels and to have the mastoid cavity free of blood and debris before the periosteal flaps are brought into place. The posterior auricular wound is then closed by vertical mattress silkworm-gut sutures. The membranocartilaginous flap is held in place by packs. The after-care is the same as for all mastoids.

Lipid Composition of Leukocytes in Leukemia—Boyd determined the lipid composition of the white blood cells, by oxidative micromethods, for nine patients with chronic myelogenous leukemia, eight with chronic lymphatic leukemia, one with acute myeloid leukemia, two with Hodgkin's disease and thirty normal adults. He found that the phospholipid and free cholesterol in the blood leukocytes are decreased in chronic lymphatic leukemia and increased in chronic myelogenous leukemia, and, of the two the most marked change occurs in the phospholipid fraction. As a result of these differences, total fatty acids and total lipid are lower in the lymphatic than in the myelogenous type. Owing to the difference in free cholesterol, the total cholesterol in the leukocytes is lower in chronic lymphatic leukemia than in chronic myelogenous leukemia. There are no consistent changes in the neutral fat or in the cholesterol esters, the latter being low in most blood leukocytes. The range of values for the total lipid in the leukocytes of

normal adults is sufficient to include all the values found in leukemia. In general, the values in chronic lymphatic leukemia fall in the lower part of the normal range, and the values in chronic myelogenous leukemia in the higher part. When this fact is compared with the previous observations that the lipid of the granulocytes tends to be higher than that of the lymphocytes, it appears that the differences in leukemia are due to differences in the relative percentages of lymphatic and myeloid types of cells in the buffy layer of blood, and not to a change in the metabolism of the blood leukocytes in leukemia.

Acquired Resistance to Tuberculosis—Reichle and Gallavan observed eighty-one cases, eight cases of primary tuberculous infection and seventy-three cases of reinfection. The patient who has a primary tuberculous infection usually dies not because of a pulmonary or intestinal lesion but as a result of hematogenous dissemination from that point. The Negro patients in the authors' series were a factor definitely tending to decrease the number of cases of lymphatic and hematic blockade. Thus, although 73.1 per cent of the white patients belonged in the group in which a "lymphatic block was present," only 44.1 per cent of the Negroes were represented in this group. In the group in which a hematic block was present the Negroes were represented by 58.5 per cent and the white patients by 71.6 per cent. Almost half of the Negroes (47 per cent) had subacute pulmonary tuberculosis, whereas almost half of the white patients (43.9 per cent) had chronic fibrous pulmonary tuberculosis. The type of disease is of distinct importance in the determination of lymphatic and hematic blockade, for the incidence of efficient lymphatic blockade rises from 30 per cent in cases of subacute pulmonary tuberculosis to 90.9 per cent in cases of chronic fibrous tuberculosis, the incidence of efficient hematic blockade being 45 and 77.2 per cent, respectively. Reisner's observations that blockade against an extrapulmonary lesion is less efficient than that against a pulmonary lesion is perhaps suggestive that in 50 per cent of the cases of extrapulmonary lesions there was a break in the lymphatic blockade and in 75 per cent a break in the hematic blockade. That chronic tuberculous disease of the lungs is rarely associated with the same condition in any other organ, however, is shown by the fact that in only two cases was there associated pulmonary and extrapulmonary disease. These results must be interpreted as a manifestation of resistance

used in the study. Antitoxin titrations of serum show that the response to two doses of plain toxoid is distinctly better than the response to one dose of the alum precipitated toxoid. Of those receiving one dose of alum-precipitated toxoid only 44 per cent developed more than 0.01 unit, whereas 80 per cent of those receiving two doses of plain toxoid developed more than 0.01 unit of antitoxin. Only 11 per cent of those tested showed antitoxin increases at the ten to twelve week titration when compared with the four to five week titration, and 14 per cent of a control group showed antitoxin increases in from one to four months with no artificial antigenic stimulus other than the Schick test. For the comparison of the antitoxinogenic value of diphtheria antigens it would seem advisable to establish as short a period as possible to measure the antitoxin response and to include a control group, particularly if the test group resides in an institution with a possible diphtherial environment.

Psychiatric Implications of Endocrine Disturbances—Tarumian believes that approximately 5 per cent of all mental deficiency is caused by glandular irregularities either of the inherent type or due to some infection received in intra uterine life. Glandular treatment of the mother, particularly in the thyroid cases in which there is a hypofunctioning will often prevent the condition from arising in the child. Early thyroid treatment will result in at least a near normal individual but the treatment must be instituted at least before the second year of life. All deviations from the normal produce mental traumas that result in maladjusted individuals, if not properly treated. This is particularly true in the sexual field, as propagation being one of the strongest instincts in human life inability to carry on the function results in a marked feeling of inferiority with a compensatory reaction resulting in all types of abnormal behavior. If abnormal individuals find it impossible to obtain equality through social methods, antisocial methods will be used. The boy who is different from the crowd because of some glandular bodily deformity broods back and finally seeks relief from his pent up emotions by seeking attention from the crowd. Physical deformity in adolescence is well recognized as one of the important etiologic factors of juvenile delinquency. Antisocial habits are thus formed which continue into adult life. Hypersecretion of certain glands causes a physical and mental unrest forcing the individual to seek new activity and excitement. He may resort to drugs and alcohol as a relief from the abnormal drive. Should the individual not receive relief through antisocial acts he becomes introspective and possibly introverted. Neuroses and psychoses develop readily. They seek compensation and excuses for their own inadequacy. Psychiatrists have been inclined to scout the theory that there is such a thing as functional insanity. Some feel that all these conditions are due to glandular disturbances. The delicate yet at present vaguely understood relation between the endocrine

Plain and Alum-Precipitated Toxoid—Schuhardt and Cook compared the antitoxin response to one dose of alum-precipitated toxoid and two doses of plain toxoid in persons having less than 0.01 unit of original antitoxin. The alum-precipitated toxoid contained 15.5 Lf units (the volume of toxin flocculating with one unit of antitoxin) per cubic centimeter and was prepared from the same lot as the plain toxoid (17 Lf)

the sympathetic nervous system and the glands of internal secretion make it extremely difficult to arrive at any definite conclusion. Since glandular conditions are often amenable to treatment before the period of puberty, it is essential that the diagnosis be made early and treatment instituted. Examination for abnormalities of the glandular system should be carried on on all children, even as their eyes and throats are examined for pathologic manifestations.

Preparation of Shiga Dysentery Vaccines by Irradiation.—Moore and Kersten investigated the possibility that the changes accompanying the killing of bacteria with heat are not identical with those produced with x-ray killing and that a vaccine prepared by irradiation of organisms with soft x-rays might be less toxic than one prepared by killing with heat, yet retain all its antigenic properties. The bacteria were prepared for irradiation by wiping off eighteen-hour slant cultures of *Shigella dysenteriae* (Shiga) and bringing the resulting suspensions in salt solution to a turbidity of 500 on the Fuller scale. In order that the suspension during irradiation might occupy a small enough space to be placed in the most intense part of the x-ray beam near the focal spot of the tube, it was concentrated by centrifugating for ninety minutes at 4,000 revolutions per minute, the supernatant liquid being decanted and resuspended in 1 cc of sterile sodium chloride solution. These concentrated suspensions were irradiated in small glass dishes placed at a distance of 5 cm from the focal spot of a copper target gas x-ray tube (Kersten 1934) whose radiation had the K α (1.54 angstroms) and the K β (1.38 angstroms) lines of copper as its most intense parts. The tube was operated at 38 peak kilovolts, with a current of 20 milliamperes, and the time of irradiation varied from thirty to 300 minutes. After irradiation the suspensions were made up to 10 cc. with sterile sodium chloride solution and tested for sterility before use. As a test for the antigenic power of the x-ray vaccines rabbits were given 0.4 cc. of living organisms intravenously. Control animals were given equal doses to determine whether the toxicity of these amounts was sufficient to kill. Of thirty animals receiving from 1 to 4 cc. (1 cc. doses) of vaccine irradiated from thirty to 100 minutes, seventeen died after receiving from one to three inoculations and thirteen survived the test dose of living organisms. Of fifteen animals receiving from 1 to 4 cc. (1 cc. doses) of vaccine irradiated for from 120 to 300 minutes two died as a result of intercurrent infections and the remaining thirteen survived the test dose for immunity. All control animals receiving heat-killed or living organisms died within from twenty-four to thirty-six hours after inoculation. It appears that vaccines receiving large doses

of x-rays are rendered nontoxic and retain their antigenic properties, while vaccines receiving small doses of x-rays, even though these doses are more than sufficient merely to kill the organism, produce vaccines that are still toxic.

Progress in Anesthesia in 1935 R. F. Sheldon Boston—p 1246

Alkalosis Complicating Treatment of Peptic Ulcer.—Jeghers and Lerner cite three cases of peptic ulcer in which treatment by the usual alkaline and Sippy regimen resulted in the development of hypochloremia and alkalosis. This syndrome is known to follow persistent pyloric obstruction. It is not so well appreciated that it may also develop without organic obstruction if alkaline powders are given in the presence of impaired ability of the body to utilize basic ions. Persistent vomiting, renal disease, anemia, hematemesis, low salt intake, excessive perspiration, liver disease and excessive doses of alkalis can all impair the acid-base regulating mechanism. Persons with impaired renal function are invariably sensitive to small doses of alkalis. It seems probable that alkalosis can develop in persons with normal renal function only if one or more additional factors besides excessive intake of alkalis are present. Persistent alkalosis can impair renal function by causing calcification or tubular nephritis. Nitrogen retention invariably accompanies alkalosis and hypochloremia. A characteristic clinical as well as laboratory picture develops which makes the diagnosis relatively easy. At first the symptoms may be vague, such as mild gastric disturbances followed by a distaste for milk, nausea and vomiting, associated with abdominal pain. The individual often shows peculiar mental deviations. Soon after, severe headache, quite frequently in the occipital region, or manifest as a sense of pressure on top of the head, may develop. Dizziness or a sensation of light-headedness, marked on motion of the head, commonly appears. Aching or cramplike pains in the muscles or joints are characteristic. Tingling sensations in the extremities may appear. Spasms and later definite spontaneous tetany may develop. The more severe cases often show slight fever, rapid pulse, slow respirations, flushed face with injection of the conjunctivae and dehydrated skin. Reflexes are usually hyperactive, and sensory hyperesthesia may develop. At times, rather than spastic phenomena the patient may show weakness, followed by prostration and drowsiness. Death follows eventually if treatment is not instituted. At the onset the urine is alkaline, increased in amount (occasionally up to 2,000 or 3,000 cc.), with low fixed specific gravity and often containing traces of albumin. Later the urinary output diminishes. The phenolsulfonphthalein test reveals a depression to as low as 10 per cent or less excretion in two hours. The blood chlorides may drop from 500 mg to a level of 350 mg per hundred cubic

centimeters Enough sodium chloride should be given to keep the chlorides at a high level The blood nonprotein nitrogen rises characteristically and often reaches values of 100 mg or more A valuable test in the diagnosis of alkalosis is the estimation of the alkali reserve of the blood, which usually shows a marked rise, especially in the more severe cases Sodium chloride therapy is highly successful

Polyglandular Disease—Crile points out that there is no organ that stands by itself and functions as if it had rented space in the human body and ran a show to suit itself Every organ is tied up with other organs, and the organism as a whole functions by virtue of the various parts played by this or that organ All the organs are coordinated by the only tissue of the body that can be conditioned—the nerve tissue. Therefore it is impossible to think of nerve tissue, whether it be brain, spinal cord, a nerve fiber, the sympathetic chain or the sympathetic complex, as performing a function by itself alone. In attacking the various diseases peculiar to civilized man in particular, one should attack them by attacking a neuroglandular group rather than by an attack on a single organ. Exophthalmic goiter is a good example of a neuroglandular disease In twenty-three cases of primary exophthalmic goiter the author did a primary denervation of the adrenal and the entire disease disappeared, including the hyperplasia, sweating and emotionalism Neurocirculatory asthenia closely resembles hyperthyroidism It presents a pure example of a pathologic physiology in the adrenal-sympathetic system Therefore it should be cured by denervation of this system

Autogenous Vaccine Therapy in Pediatrics—Bloom used autogenous vaccines in forty-six cases of common cold, thirty-five of asthma thirty-three of pyelitis and eleven of furunculosis Cold vaccines gave either good or fair results in only 28.4 per cent of the cases Immediate protection is the exception to the rule Small initial with increasing doses not exceeding 1 cc. at frequent intervals and over a long period, are advocated. The seasonal change of the flora of the upper respiratory tract justifies additional observations as to what organisms shall be included and the further consideration of a perennial vaccine In selected cases, vaccines in bronchial asthma gave 25.7 per cent cures and noticeable improvement in 40 per cent The bacterial focus or foci of infection must be sought, the method of culturing should follow a definite routine in every case. Deductions warrant continued use of vaccines in the treatment of bronchial asthma of bacterial origin The result of vaccine therapy in the cases of resistant pyelitis in which other treatments except cystoscopy have been used with negative results gave a 45.5 per cent cure. Vaccines appear especially effective when more than one organism has been removed The treatment of pyelitis by vaccine should be encouraged and continued. There was a 100 per cent cure in the eleven cases of furunculosis.

Ileus Associated with Strongyloides Infestation.—Nolasco and Africa report a fatal case of intestinal obstruction due to paralytic ileus associated with a severe infestation with *Strongyloides stercoralis* The discovery of filariform larvae in the muscular and serous coats of the jejunum, ileum, appendix, large intestine and liver tends to confirm the theory advanced by Gage, Ophüls and Nishigori that reinfection in strongyloidosis can take place in the intestine Traumatism was evident and was shown by marked congestion and swelling of the mucosa of the small intestine and the formation of small submucous abscesses in the large intestine. The vomiting and abdominal distention and tenderness with tympanism before death and the postmortem observations of intestinal obstruction without any apparent gross organic cause can be explained only by a massive invasion of the intestinal wall The weak condition of the patient and the stasis of the intestinal contents possibly induced a larger number of the infective forms to penetrate the intestinal wall That there was an overwhelmingly extensive infestation was also shown by the abundant larvae found in the feces at necropsy That the presence of the larvae in the deeper layers of the intestinal wall and liver was not due to postmortem migration is indicated by the presence of inflammatory changes such as tubercle formation around the larvae In spite of the usual absence of alarming symptoms, strongyloidosis must be regarded as a serious disease The patient s infestations had been observed since admission to this colony in June 1930 His death could not be attributed to any cause other than the heavy infestation with *Strongyloides*

Treatment of Neurosyphilis with Monkey Malaria.—Not having a suitable case of tertian malaria available at the time, Chopra and Das Gupta treated two patients suffering from optic atrophy, with a history of syphilis and a moderately positive Wassermann reaction, with monkey plasmodium. The first patient showed a marked refractoriness to infection with Plasmodium Knowlesi. After the initial inoculation there was a long incubation period, the temperature was never high and the infection died out spontaneously within a week. A second injection of 0.8 cc. of blood was tried without infection resulting whereas the same dose from the same animal given to the other patient at the same time produced alarming symptoms. The complete failure of the second injection may be ascribed to a degree of tolerance being acquired by the patient from the previous infection. In the second case there was a high temperature with a low parasite count similar to that seen in quartan infection, and marked cerebral symptoms developed which were easily controlled with small doses of atabrine and quinine. There is no doubt that the reaction of the pupils to light is more brisk and the mental condition of the patient has greatly improved. He is no longer apathetic and is now demanding to go to his home. His speech, though still blurred, is clearer than before. An ophthalmic examination showed that so far as the fields of vision and the appearance of the retina are concerned there is no change. The patient is being kept under observation. It appears that an attack of monkey malaria in human subjects confers immunity or a marked degree of tolerance to reinfection. How long this tolerance is maintained is now being studied.

Observations on Treatment of Tetanus.—Freeman cites five cases of tetanus four with short incubation periods and one of intermediate length, in four of which recovery occurred

and one of which was fatal. The death was due to circulatory failure but was directly attributable to bronchopneumonia. Serum was given freely intravenously and intramuscularly. The dosage was from 160,000 to 200,000 units in each case. Chloral hydrate was used partly in one case. Phenobarbital, especially phenobarbital sodium, was employed in all the cases with excellent results. In the third case tribrom-ethanol was tried, with remarkable sedative effect. In the fourth and most convulsive case tribrom-ethanol was employed night and morning for thirteen days, producing almost continuous anesthesia. The dose given was midway between the total anesthetic dose and the obstetric dose for the patient's weight. This patient received in all 997 cc. of the drug. The result was excellent. In the fifth case it was employed by night for twelve nights. Feeding was chiefly by dextrose solutions of various kinds. With patience, especially when half awake, the patients could be induced to swallow slowly. The conclusions reached are that phenobarbital is of great value and much superior in tetanus to the older hypnotics, and that tribrom-ethanol appears to be a drug of inestimable value. It stops the spasm greatly, relaxes the rigidity, and substitutes sleep and rest for the most intense agony of body and anxiety of mind.

Abdominal Manifestations of Arterial Disease.—Lakin asserts that in considering the abdominal manifestations of arterial disease it is essential to distinguish between the effects of disease of the abdominal aorta and its branches and a group of symptoms encountered in certain cases of disease of the coronary arteries of the heart. In recognizing cases of coronary occlusion in which pain is experienced within the abdomen rather than within the chest, the importance of an exact history both of the present and of any previous attack cannot be stressed too highly. It is exceptional for the pain to be entirely abdominal, and the sufferer in addition to his complaint of epigastric pain will often state that he also feels pain behind his breast bone. It may be possible to obtain a past history of retrosternal pain coming on after walking a distance and causing so much distress that the sufferer has to stand still till relief is obtained. In an attack the presence of dyspnea accompanying the abdominal pain would point strongly to a cardiac rather than to an abdominal cause. Examination of the heart may show characteristic abnormalities thus signs of enlargement may be present the first sound of the heart may be deficient in muscular tone, or possibly a pericardial rub is audible. A sphygmomanometric reading reveals an abnormally low blood pressure, and specific electrocardiographic observations such as inverted T waves, a P-dee curve or intraventricular or auriculoventricular block may confirm the diagnosis. Within twenty-four hours of the onset pyrexia and leukocytosis are usually to be found. Acute coronary occlusion with cardiac infarction when giving rise to abdominal pain may be confused with acute abdominal conditions, such as perforated peptic ulcer, biliary colic or acute pancreatitis, yet an exact history and careful clinical examination usually suffice to make the distinction fairly certain. Pain and vomiting may be encountered in either but complete absence of rigidity in the abdominal muscles would be strongly in favor

of a cardiac origin of the pain. There are cases in which angina and cholecystitis coexist and in which surgical treatment of the diseased gallbladder has led to some alleviation of the anginal attacks. In the group of cases in which cholelithiasis gives rise to symptoms resembling abdominal angina the existence of dyspnea would strongly favor a coronary origin for the pain, whereas rigidity of the right rectus abdominis would inculpate the gallbladder. A careful examination of the heart should be carried out in all such cases and a cholecystogram may be of service.

Septicemia with *Streptococcus Viridans*—Marquary and Huguet describe a clinical syndrome caused by *Streptococcus viridans* and characterized by a septicemia with streptococci without involvement of the heart and carrying usually a favorable prognosis. These septicemias should be differentiated from those caused by hemolytic streptococci, clinically as well as bacteriologically. A case was reported of a woman, aged 30, in whom the disease was characterized clinically by two periods. The first, from the first to the ninth days, was characterized by sudden onset, even temperature, herpes and no other objective signs. The second from the ninth to the twentieth days, was characterized by oscillating temperature, splenomegaly, a splenopneumonic syndrome and for one week purulent expectoration. *Streptococcus viridans* was found in the blood on the ninth day of the disease, but search for the port of entry for the streptococcus was not satisfactory, although it was most probably the tonsils. The prognosis of streptococcal infections of this nature is usually good and the course follows neither that of a bacterial endocarditis nor that of a hemolytic streptococcal infection.

Dysglycemias of Old Age—According to Renaud and Petit-Maire, diabetic conditions are encountered frequently in old age and form a perfectly homogeneous group in which clinical and etiologic individualization offer a benign prognosis. Several case reports indicate that most of the patients of this age group who develop glycosuria fall in the class of those having a syndrome rather than a disease, which the authors prefer to call dysglycemia. These patients display common characteristics from the standpoint of appearance, discovery only during a routine examination, association with vascular, renal and nervous degenerations and benign evolution and prognosis. Treatment should be directed toward correcting the functional disorders or at least lessening their frequency and toward regulating the manner of life of the individual, especially his activity and nutritive regimen.

Bilirubin Test in Diagnosis of Hemorrhagic Diseases—Boudin and Panayotopoulos performed the classic direct van den Bergh reaction on the serum of a number of patients with hemorrhagic diseases of the nervous system to determine

the importance of bilirubin in differentiating between cerebral hemorrhage and cerebral softening. The results of these tests on thirteen patients were inconstant. In any case, the test seemed to have no special value in the differential diagnosis between hemorrhage and cerebral softening. In spite of this negative conclusion it was possible to say that, if the bilirubin test was strongly positive, hemorrhage was likely.

Bronchoscopy in Diagnosis and Treatment—Seeliger shows that, owing to improved technique and instrumentation, the indications for bronchoscopy have been greatly increased. Every sign of bronchial obstruction makes bronchoscopy advisable. He thinks that, whenever there is coughing, dyspnea, asthma-like wheezing and contraction of the ribs, bronchoscopy should be resorted to, for in such cases a foreign body may be detected and diagnostic errors avoided. He cites a number of cases in which foreign bodies were overlooked and the patients were treated for a long time on the basis of an erroneous diagnosis. He shows that bronchoscopy cannot be dispensed with in pulmonary atelectasis. He differentiates between true, acute atelectasis and secondary atypical atelectasis. He says that bronchoscopy has therapeutic value only if it reveals a growth or an obstruction, or if a complicating suppuration has developed that has to be drained. Its diagnostic significance is of much greater importance, particularly in cases in which the advisability of a thoracoplastic intervention or of a lobectomy has to be decided. The author discusses thoracoscopotherapy in pulmonary abscesses and in bronchial dilatations. Twelve cases of acute putrid pulmonary abscesses were treated with this method. The abscesses had existed for from four to eight weeks and the treatment required from six to twelve weeks. The number of bronchoscopic sessions varied between four and eight. The author says that bronchoscopotherapy as a rule effects cure in from 70 to 75 per cent of the acute pulmonary abscesses. However, even if bronchoscopy does not effect cure, it is a necessary preparatory measure for a surgical intervention. This applies particularly to the chronic abscesses, in which cure is much more difficult than in acute abscesses. In bronchial dilatations, the therapeutic results of bronchoscopy vary considerably. Some bronchiectases, particularly the relatively new ones that developed as sequels to pulmonary abscesses were cured. In a material of fifty cases complete anatomic cure was obtained in 14 per cent and improvement in 80 per cent, while in 6 per cent the treatment was a failure. Discussing the use of bronchoscopy in pulmonary tuberculosis the author says that it was long regarded as inadvisable. His observations do not bear this out, except that he advises against it during acute exacerbation and hemoptysis. Bronchoscopy gives exact information about the condition of the tracheobronchial tree and it may be of therapeutic value in the removal of intrabronchial tuberculous formations or in the aspiration of a complicating suppuration.

Chloride Content of Blood in Tuberculous Meningitis—Martin and his associates investigated the chloride content of the cerebrospinal fluid and of the blood in patients with tuberculous meningitis. On the basis of their observations they reach the following conclusions: 1. There is a relationship, but not a mathematical one, between the chloride content of the cerebrospinal fluid and that of the blood. 2. The decline in the chloride content of the cerebrospinal fluid during meningitis is explained by the reduction of the blood chloride. This decline which is particularly great in the course of tuberculous meningitis is explained by the considerable hypochlo-

emia which attains values that are exceptional for clinical conditions. 3 Parallel with the hypochloremia there appears in tuberculous meningitis a hypochloruria which in some cases may have diagnostic value. 4 The reduced chloride contents of the cerebrospinal fluid and of the blood in tuberculous meningitis are not the result of a loss but rather the consequence of a retention of chlorides in the tissues.

*Vagal Mechanism of Hypoglycemia Secondary to Administration of Hydrochloric Acid by Mouth F Romeo—p 596

Hypoglycemia Secondary to Administration of Hydrochloric Acid—Romeo made determinations of glycemia in patients suffering from hypochlorhydria or anachlorhydria but who were otherwise normal. All determinations were made on patients with a fasting stomach and repeated every fifteen minutes during the two hours following administration of a certain treatment that varies in the three different days of the test. The treatment consisted in oral administration of 150 cc. of a 6 per cent hydrochloric acid solution on the first and second days. On the second day, however, it was preceded by an injection of 1 mg of atropine. On the third and last day the patients were given only an injection of 1 mg of atropine. The administration of hydrochloric acid by itself produced hypoglycemia, which failed to take place when the acid was given after the atropine injection. The simple injection of atropine produced hyperglycemia. The author states that in normal conditions the gastric wall is directly stimulated by hydrochloric acid during the process of digestion. The stimulation produces gastric reflexes, which are transmitted through the vagus nerve to the pancreas. The reflex stimulation of the pancreas results in an increased secretion of insulin by which glycemia is maintained within normal limits. The threshold of the production of the gastropancreatic reflexes is lowered in patients suffering from hypochlorhydria and the reflexes take place by stimulation of a hypochloric gastric secretion. The increased concentration of hydrochloric acid in the gastric secretion, following the administration of the acid, results in the increase of gastropancreatic reflexes, in which hyperinsulinemia and consequent hypoglycemia originate. As atropine paralyzes the parasympathetic the vagal reflexes fail to reach the pancreas when hydrochloric acid is given after the atropine injection. These facts account for the lack of modification of glycemia and the presence of slight hyperglycemia when the patients were given atropine followed by hydrochloric acid. The presence of hyperglycemia following administration of a single injection of atropine solution points out the part of the blockage of the vagal reflex in the production of hyperglycemia in these patients. The author states that his results indicate the vagal nature of the gastroduodenopancreatic reflexes.

Phenolsulfonphthalein in Treatment of Arthritis—Boschi reports satisfactory results with intravenous injections of phenolsulfonphthalein in the treatment of endogenous chronic arthritis. The injection is given by the following technic. A few cubic centimeters of cerebrospinal fluid is removed just before the injection is made. The injection is prepared by dissolving between 3 and 9 mg of phenolsulfonphthalein in 1 or 2 cc of double distilled water and then made slightly alkaline. Just before the intraspinal injection is made, 1 cc of cerebrospinal fluid is withdrawn and added to the solution of phenolsulfonphthalein. The injection produces high fever which lasts for a few days in the course of which the development of arthritis is greatly and favorably modified. The pain

ful inflammatory and muscular disturbances subside and the patient completely recovers at the subsidence of the febrile reaction. One injection usually is sufficient, but it is advisable to repeat it within two or three weeks as a consolidation for the results of the first injection. None of the author's patients had a recurrence.

Allergic Gastropathy with Pyloric Syndrome—Bonorino Udaondo and Sanguinetti's patient, aged 29, suffered from asthma in childhood. At present he was suffering from urticaria and pain in the epigastrium and a condition that gave the clinical and roentgen picture of complete spasmodic occlusion of the pylorus. Injections of 0.5 mg of atropine twice a day controlled the condition in three days, after which he was given 10 cc of his own blood twice a week until he had received fifteen injections. One year later the disorder recurred, but after the patient had been treated by the same method as before it subsided. After this the patient was successfully treated by nonspecific sensitization with epinephrine, peptones and a milk diet. The authors state that calcium, atropine and epinephrine treatments are useful as coadjuvants of allergic gastropathies but that desensitization does not give the best results in controlling the allergic condition. Nonspecific sensitization by autohemotherapy, protein therapy and pepsin therapy, in association with drugs regulating the sympathetic system and exclusion of certain foods from the diet, are of benefit to the patients. However more interesting and promising are the results of specific sensitization as reported by Thiers and Chevallier in the *Presse medicale* May 2, 1936. The treatment in short consists in the subcutaneous injection of an antigen obtained by ultrafiltration of the substance to which the patient has an allergic reaction. This substance is removed from the stomach by catheter one hour after having been ingested and then prepared by ultrafiltration, dilution of the ultrafiltrate in artificial serum, and neutralization and finally tyndallization of the product obtained. This treatment produces specific sensitization.

Influenzal Polyneuritis with Acute Ataxia Cases A Cicinelli and M Ilari—p 2006

Diagnosis of Cancer of Testicle—Iacapraro states that early in the development of testicular cancer there is an asymptomatic period characterized by the presence of a small zone of induration in an almost normal testicle with normal epididymis, spermatic cord, tunica vaginalis and scrotum. As the induration may also be caused by syphilis, the failure of intense antisyphilitic treatment, for about ten days, indicates immediate surgical examination of the testicle, which is made under local anesthesia and includes small incision of the scrotum, exteriorization of the testicle, small incision of the tunica vaginalis and visual examination of the tunica albuginea, which in testicular cancer is abnormally vascularized. The diagnosis of tumoral testicle is made by the lack of adhesion of the tunica vaginalis to the testicle and the normal condition of the membrane and of the epididymis, detected by pinching these structures between the thumb and the forefinger. If there is no abnormal vas-

cularization of the tunica albuginea, exploratory orchotomy and biopsy are indicated. Immediate castration is indicated (1) if the tunica albuginea is abnormally vascularized and (2) in cases of enlarged testicle the size and character of which were not modified by intense antisiphilitic treatment. The author emphasizes the importance of early diagnosis and treatment of testicular cancer because the development of the tumor is simultaneous with that of metastases to the semilunar and aorticorenal ganglions through the lymphatic routes, as soon as ganglionic metastases exist, treatment is useless. Sometimes roentgen irradiation results in reduction of the tumor and its complete disappearance, but it does not modify the course of progressive cachexia. Roffo's test gives only 50 per cent of positive results in cases of testicular cancer. The patients in the author's group were seen late in the development of cancer, when the tumor was already present and supra-abdominal adenopathies were manifested, that is, at a time when satisfactory results are not obtainable.

Leads from Thoracic Wall in Clinical Electrocardiography—Hecht shows that a number of electrocardiographic curves obtained from the customary leads cannot be subjected to an exact clinical evaluation. The question arises whether with leads from the thoracic wall it will be possible to explain these obscure conditions. Of the various systems that have been devised recently to take leads from the thoracic wall, the author considers that of Wilson the best and he suggests that a fourth and fifth lead be added to the customary three. He regards as especially suitable for the leads (1) the third rib at the right sternal edge (fourth lead near the right side of the heart, over the base and near the auricle), (2) the sixth intercostal space in the left anterior axillary line (fifth lead near the left side of the heart, over the apex and distant from the auricle). The author found that, with the aid of these two leads, normal hearts always produce the same typical curves, regardless of whether they are of the levotype, the dextrotype or of the normal axial position. The pathologic heart, however, shows over the thoracic wall entirely different conditions. Thus it is always possible to differentiate the "predominating curves" into those of simple deviation of the axis of the heart of normal persons and those indicating pathologic changes of the myocardium in patients with heart disease. The fourth lead is near the auricle, whereas the fifth lead is nearly a pure ventricular electrocardiogram. Beginning changes of T and of ST waves for instance in auricular fibrillation, can be clearly demonstrated in the fifth lead. In addition to this, the new leads make it possible to differentiate more clearly the onset and extent of the toxic impairment of the myocardium (digitalis). The fourth lead, which is near the auricle, demonstrates clearly biphasic P waves. In twenty-two patients in whom the electrocardiographic aspects conflicted with the clinical examinations the new leads clarified matters in that they revealed conditions which corresponded to the clinical aspects.

Thrombocytic and Leukocytic Pictures in Tetanus—Arneith maintains that there exists in tetanus no neutrophilic stage of defense with deviation to the left. This indicates that the toxin of tetanus (in contradistinction to most other infectious diseases) has no neutrotropic affinity. The qualitative blood picture of the lymphocytes shows likewise a different behavior in tetanus than in the other infectious diseases in which they usually show a deviation to the right. In tetanus, the lymphocytes show, in contradistinction to the neutrophils, a decided deviation to the left usually with simultaneous increase in their absolute values. The author describes the

behavior of the thrombocytes in several cases of tetanus. His studies on the thrombocytes revealed that the toxin of tetanus does not cause great qualitative changes. There is only a slight deviation to the left (in the direction of the young forms), in that the larger roundish forms and the simple longish forms show a slight increase. In addition to this there is a deviation to the left as far as the size of the thrombocytes is concerned ("macroreaction").

Tumor Cells in Sternal Puncture—Rohr and Hegglin say that in their study of bone marrow specimens, which were obtained by sternal puncture, they often observed cells and groups of cells that are found neither in the normal marrow nor in the marrow of patients with diseases of the blood. Careful studies revealed that some of these cells had the characteristics of tumor cells. The authors resorted to puncture of the sternum in seventy-four cases of malignant tumors, of which twelve showed metastases in the bone system. In ten of these twelve the sternal punctate contained tumor cells, but in the two other cases the demonstration failed, in spite of the fact that the necropsy demonstrated sternal metastases. The authors classify tumor cells in the sternal punctate in the parvicellular and macrocellular types. Parvicellular types are found especially in cases of bronchial carcinoma, macrocellular types mostly in carcinomas of the prostate and of the stomach. However, the tumor cells in the sternal punctate permit no definite conclusions as regards the location of the primary tumor.

- *Reticulocyte Count in Blood Diseases During Childhood W. Heuberg—p 311
- *Clinical and Etiopathogenic Aspects of Chorea Minor O. Kröner—p 329

Reticulocyte Count in Blood Diseases in Children—According to Heuberg, the clinical significance of reticulocytes is still in dispute, but the majority of investigators agree with Naegeli, who sees in their appearance the most reliable and earliest sign of a hyperfunction of the bone marrow. In accordance with this they are regarded as one of the most important criteria of blood regeneration in anemias and of the regenerating action of various physical, hormone and chemical therapeutics. Following a discussion of the factors that increase the reticulocytes, of the morphologic characteristics of the reticulocytes and of the technic of staining and counting them, the author gives his attention to the various disorders of childhood, in which the regenerative activity is indicated by fluctuations in the number of the reticulocytes. First he discusses cow's milk anemia, giving the clinical history of two typical cases. In one case the initial value of the reticulocytes was relatively high and, in accordance with this, the increase during the process of recovery was comparatively slight. In the other, rather mild, case the stimulus seemed too slight to tax the reticulocyte reserves noticeably. The author discusses a case of nonregenerative anemia in idiocy. The anemia developed after several years of an exclusive cow's milk diet, the child refusing any other food, and terminated fatally. In this case the number of reticulocytes was comparatively small (only 15 per thousand before death). The author thinks that the prolonged existence of the cow's milk anemia and the extreme depletion of the iron depots was the reason the anemia assumed secondarily a nonregenerative character. In goat's milk anemia he found that blood regeneration was earlier and more severely inhibited than in feeding with cow's milk. Goat's milk anemia responds noticeably to liver therapy, and the rise in reticulocyte values is occasionally greater than during the remission in pernicious anemia. In a case of anemia resulting from nutritional disturbances, a considerable increase in reticulocytes was observed simultaneously with the improvement in the dyspepsia. In celiac disease although the anemia was rather mild there was a considerable increase in reticulocytes soon after treatment was begun. In postinfectious anemia the improvement was likewise accompanied by a rise in the reticulocyte count. Observations in cases of hemolytic icterus and hemolytic anemia corroborated reports in the literature in that extremely high reticulocyte values were noted. The author says that pernicious anemia is the only type of anemia in which it

reticulocytes do not show higher values. However, as soon as remission sets in they increase greatly. In a case of lymphatic leukemia that terminated in death the reticulocyte count was low (12 per thousand) in spite of the severe anemia that existed. In children with exudative lymphatic diathesis the reticulocyte count, like the anemia, remained stationary for a considerable period.

Chorea Minor—In a study of 122 cases of chorea minor, Kröning reached the following conclusions: 1 Chorea minor is a neuro infection of independent etiologic significance. 2 The viruses of chorea and of rheumatism are related or even identical. This is indicated by the frequent concurrence of chorea and rheumatism, the great incidence of the disorders during the spring months and in children between the ages of 8 and 12 years, the pathologic changes in the heart and pharynx, identical blood pictures and Aschoff's nodules. 3 In consideration of the uncertainty and variety of the bacteriologic observations in chorea minor, it is impossible to speak of a specific organism for this disorder. 4 The rheumatic virus has the greatest choreogenic action, but other viruses may cause chorea by their exacerbating action on rheumatism. Toxic chorea is a choreatic syndrome that can be produced by various toxins. 5 The reaction of the nervous system that is the basis of the development of chorea minor is of an allergic nature, as in the case of rheumatic infections. 6 Predisposing factors for the development of chorea minor are heredity, poor living conditions, tonsillitis and other conditions that reduce the resistance of the organism. 7 The chorea virus is characterized by considerable dispersion adsorption and neurotropism. The dissemination of the virus in the central nervous system is possible in two ways, by the cerebrospinal fluid and hematogenously. 8 In chorea minor the process is not limited to the striatal apparatus and the cerebellar tract but spreads to the entire nervous system, cerebral cortex, cerebellar system, brain stem and nerve trunks. 9 The hyperkinesis is caused by the action of the virus, the shifting of the threshold for motor stimuli and the constitutional characteristics of the organism. 10 In addition to the infectious cause, a hormone factor plays a part in the pathogenesis of chorea minor (high incidence of the disorder in girls, in pregnant women and during the spring months). 11 The therapy of chorea minor is anti-infectious, sedative and symptomatic.

Acute Pulmonary Edema During Birth.—Hesse points out that under the term "acute pulmonary edema in pregnancy" a few cases have been reported in which acute pulmonary edema developed with more or less severe symptoms of shock, although there were no signs of cardiovascular disease or of eclampsia. He gives the histories of three fatal cases in which the necropsy revealed acute pulmonary edema. His cases show the following typical symptoms. During parturition or immediately after delivery, there appears a threatening collapse with severe circulatory disturbance, cyanosis, cold sweat, small pulse, dyspnea, pulmonary stasis and pulmonary edema but the patients do not lose consciousness or have convulsions. The author points out that these symptoms correspond to the clinical aspects of so-called toxic shock. He says that, in contradistinction to shock caused by nervous reflex, secondary wound shock can be traced to the so-called capillary toxins. He thinks that the theory of the elicitation of shock by capillary toxins explains the clinical processes during shock, namely, failure of the circulation in case of intact heart and, in spite of adequate central vasomotor regulation, pallor, dyspnea, pulmonary edema, inspissation of the blood, disturbances in the coagulation and the formation of edema. He points out that, if the reported cases are compared with this symptomatology, acute pulmonary edema during birth can be classified with the conditions of true shock.

Symptom of Retention of Placental Remnant.—Föderl produces maximal contraction of the uterus by intravenous injection of posterior pituitary extract, then grasps the uterus as in Crede's method and by lateral and axial movement of the four fingers that are at the posterior uterine wall a careful palpation is made of the posterior wall, the lateral portions and the tubal corners. The fundus uteri, its anterior wall and the adjoining lateral portions are palpated in such a manner that, while leaving the hands in the position as in Crede's maneuver, the free hand of the examiner explores these portions by lateral movements with the finger tips. If the uterus has the same compactness everywhere, the test is negative. However, if a depressed area or an area of reduced compactness is felt, a placental remnant has been retained. The method permits not only the detection of comparatively small remnants but also their location, and it is not dangerous for the patient. The author concludes that this test should be made in all cases of postpartum atony and whenever the inspection of the placenta makes the retention of a placental remnant seem possible.

*Clinical Method of Blood Culture for Demonstration of Organisms in Circulating Blood. H. Reichel—p. 784

Variability of Intestinal Bacteria in Nurslings.—Reuss and Hassmann describe investigations that caused them to ascribe to the variability of intestinal micro-organisms an important part in the development of enteric disturbances and of the so-called alimentary disturbances in nurslings. They gained the impression that the group of paracoli bacilli, which, standing between coli and paratyphoid, probably develop by variation and represent either temporary or permanent modifications, are an important factor in the alimentary-infectious etiologic complex. Their more or less toxic (antigenic) action could be demonstrated by different methods, by cutaneous tests, by the action on the surviving rabbit intestine and by agglutination reactions. Further it was demonstrated by culture experiments as well as by observations on animals that such mutations from the coli to the paracoli group take place within the intestine. There develop pathogenic and contagious modifications, which in turn become the source of ectogenic infections. It is probable that this mutation takes place in nurslings usually by way of the so-called endogenic infection of the small intestine, under the influence of alimentary flora. For this reason the authors think that the hitherto strict differentiation between nutritional disturbances of alimentary and of infectious origin should be dropped. The ectogenic infection with paracoli strains seems to be most effectively controlled by the administration of lactic acid milk. However, it has yet to be clarified to what extent endogenic mutation can be influenced by the composition of the food. The authors think that the clinical significance of the variability of the bacteria goes far beyond the problem that has just been touched on. They call attention to the sudden appearance of a case of scarlet fever, without any indications as to the source of infection. They think that in such cases the assumption of a modification of a streptococcus strain might be more justified than the search for a bacillus carrier, and that similar considerations might be justified in erysipelas and in diphtheria.

Demonstration of Organisms in Blood.—Reichel shows that for the diagnosis of endocarditis lenta the demonstration of the organisms in the circulating blood (usually Streptococcus viridans) is of great importance. He developed a method that is simple enough to be used by the physician without especial training in bacteriologic studies. Into each of two tubes (filled with 10 cc. of bouillon) he places a blood specimen (15 cc. into one, 2.5 cc. into the other). For greater exactness he

recommends the use of duplicate tubes (four in all). The bouillon tubes are placed in the incubator (at 37 C.) After several hours it can be observed that the erythrocytes have settled in the curvature, without the formation of a solid clot. Above the erythrocytes there is a veil of fibrin. Positive cultures show, after from eighteen to twenty-four hours (in rare cases not until the third day), bacterial cultures in the veil of fibrin. If too much blood has been placed in the tube it forms a clot, and if too little has been used the fibrin veil is absent and the bacterial colonies are on the sediment of erythrocytes. If the correct quantity of blood is used there always forms a fibrin cloud in which the organisms grow into macroscopically visible colonies. After the colonies have grown to maturity, the micro-organisms can be brought to more abundant growth by simply shaking the test tube or by transfer to blood agar or other culture mediums. The author asserts that in cases of endocarditis lenta this procedure gives positive results even if the blood slide remains sterile.

Study of Chronic Colitis—Ryss and Rotermel present a clinical and roentgenologic study of 100 cases of chronic colitis. A careful history, palpation of the intestine, examination of feces after a three-day diet of Schmidt including the determination of ammonia and of organic acids, and a roentgenologic study of the mucosal relief of the large intestine according to the method of Knothe were carried out in each case. The authors divide their material into three groups: (1) dyskinesia, (2) colitis and (3) enteritis. They designate as dyskinesia a syndrome characterized by motor disturbances of the intestine without an accompanying morphologic alteration of the mucosal relief. In a group of forty-four patients presenting dyskinesia with a duration of the condition of from one to ten years, thirty-four suffered from obstinate constipation, in seven constipation alternated with diarrhea, in one there were periodic diarrheas and in two the intestinal habit was normal. Thirty-two had attacks of colic. Functional disturbances of the vagal-sympathetic nervous system were present in twenty-eight. Feces were normal in thirty-four. Roentgenologic studies of the mucosal relief of the large intestine revealed no pathologic alterations. Thirty-one cases were diagnosed as colitis on the basis of the clinical history, examination of the feces and roentgenologic observations. The clinical symptoms were those of constipation alternating with diarrhea, diarrhea, tenderness along the course of the large intestine—spontaneous or elicited by palpation—splashing sound over the cecum and hypertonic state of the intestine. The earliest morphologic alteration in the intestinal mucosal relief in these cases is a widening of the mucosal folds and loss of autoplasmic function of the folds. The cases of acute colitis give a more characteristic picture with irregular interruptions in the markedly widened mucosal folds, fine starlike shadows and niches. The widening of the mucosal folds is caused by edema while the starlike shadows and niches represent ulcerations. In the third group of enteritis the roentgenologic studies revealed no anatomic alterations in the large intestine though its behavior was that of the irritable hypertonic type. The authors conclude that roentgenologic study of the mucosal relief is valuable in establishing the segment involved and the presence and the degree of morphologic and functional alterations of the large intestine. The study of feces establishes the degree of functional disturbances of the various segments of the large and small intestine. They suggest that dyskinesia of the large intestine based on functional disturbance of the intestine in the absence of inflammatory alterations of its mucosa be considered an independent clinical syndrome.

*Liver Diuresis as Result of Rhythmic Function of Liver F. Gerritzen—p. 101

Pathophysiology of Obesity S. Leites and A. Agaletzkaia—p. 199

An Abundant Growth of Tubercle Bacilli—After mentioning the disadvantages of other methods that are used for the purpose of obtaining a more abundant growth of tubercle bacilli, Wihman describes his own method as follows: The ordinary centrifugation tube is replaced by an especially constructed larger one, which has a flat bottom and a bottom plate that is used as a slide. This round slide is placed on the bottom of the centrifugation tube before the fluid is poured in. Following centrifugation, the fluid is poured off in such a manner that the tube is brought slowly into the horizontal position. As a rule, the round bottom slide likewise falls into the horizontal position (that is, with the top downward). If the slide should stick to the bottom it can be loosened with a platinum wire. The round slide is taken out and stained in the usual manner according to Ziehl-Neelsen. During microscopy it is placed on an ordinary slide. Sputums can be examined with this new method, provided they are first treated with antiformin or some other agent of homogenization. Comparative studies on twenty specimens of sputum proved the superiority of this method over the older ones. The author says that the round slide can be used also for other bacteria. In this connection it is pointed out that the round slide on the bottom of the centrifugation tube had been used earlier by an Italian author in the examination of the cerebrospinal fluid in chronic diseases of the central nervous system, in which the form elements are found in small numbers. The author points out further that he found why the methods that are to secure a more abundant growth of bacilli often give unsatisfactory results. He observed that the sputums contain fatty substances which, on account of their lower specific gravity, rise to the top and carry the bacilli with them. On the basis of this fact, he developed a simple method for obtaining a more abundant growth of bacilli. He places the sputum in the incubator (at 37 C.) until it is autolytically dissolved. Then it is poured into a glass cylinder and several hours later the cylinder is placed in a water bath of 80 C., which favors the rising of the fat to the surface. Following this, several loopfuls are taken from the surface layer and are placed on a slide for examination. The author recommends the combined use of centrifugation and the surface layer method.

Rhythmic Function of Liver—Gerritzen points out that on the basis of animal experiments and of clinical observations Forsgren advanced the hypothesis that the liver functions rhythmically, there being a rhythmic alternation between its glycogen storage and its bile secretion. Forsgren found that, when the glycogen content of the liver increased by 1 Gm., the weight of the liver increased by 43 Gm. From this fact he concluded that, along with the glycogen, water is stored. This conclusion was confirmed by the microscopic picture of the liver in the various stages of function. During the period of predominating assimilation, glycogen and water are stored; during the dissimilation phase the glycogen disappears from the liver and water is given off at the same time. In answer to the question as to what happens to this water the author says that it may be assumed that it will be excreted by the kidney, in that it acts as a solvent for the dissimilation products that are excreted in the urine. He made seventy-two experiments on fifty-seven persons, who drank 75 cc. of water every hour and whose urine was measured every hour for twenty-four hours or longer. It was found that the rhythmic function of the liver is reflected in the diuresis. The diminutions in the diuresis which occurred at 9 a. m., 1 p. m. and 6 p. m. the author ascribes to the intake of food because the food to be dissolved takes water from the organism; this water being detracted from the diuresis. Later experiments (on thirty-five persons) proved that the meals did in fact have this influence on the diuresis. The author concludes that his experiments proved that the rhythmic function of the liver which Forsgren proved to exist in animals exists also in human subjects.

CHOLECYSTOGRAPHY

CHAIRMAN'S ADDRESS

E. L. JENKINSON, M.D.
CHICAGO

Cholecystography, as brought forth by Graham, Cole and their co-workers, is quite generally accepted in determining whether or not the gallbladder is functioning normally. The work of Kirklin, Moore, Stewart and others has done much to prove the accuracy of the method. Through careful cholecystographic studies and with an abundance of available material, Kirklin has had an excellent opportunity to check his roentgenographic observations operatively and pathologically. Other investigators have also done much work which has substantiated the original work of Graham and Cole. Since the method was originated there has been ample time and sufficient operative and pathologic study to prove its accuracy. There is practically no procedure in diagnosis which has demonstrated so conclusively its accuracy and importance when made under proper conditions, namely, close cooperation and control of the patient from the time the dye is taken until the last film is made.

The importance of cooperation of the patient is demonstrated in many ways. First, the patient should refrain from taking any fatty foods by mouth from the time the dye is administered until after satisfactory films have been obtained. It is also important that the patient be carefully instructed regarding the importance of movement and breathing during the x-ray exposures. Slight movement will oftentimes obliterate a normal gallbladder shadow. It is not uncommon during the course of the radiographic examination to be unable to outline the gallbladder on one film but on the second film, taken immediately following, to see a normally filled gallbladder. This is usually due to movement. With this fact in mind, it is essential that the patient be informed that it is imperative that there be no movement or breathing during the x-ray exposures and that the exposures should be made as rapidly as possible to obviate any movement. The various positions in which the examinations are made have been described so thoroughly by other writers that I will not go into the details of the procedure in this paper. Occasionally it is necessary in the presence of a shadow in the right upper quadrant which is located in the area of the dye-filled gallbladder to make lateral exposures in order to state definitely whether or not the shadow is within the gallbladder. I have found the lateral examination of value in differentiating intracholecystic shadows from extracholecystic shadows.

Cholecystographic examinations were done on ninety-five individual patients. Of these forty-nine were females, forty-six were males, and the average age was 42 years. Of the ninety-five patients examined, seventy showed normal visualizations. All the ninety-five patients had symptoms thought to be due to gallbladder disease. Many interesting facts have been learned in the compilation of the material for this paper, the most interesting observation being the frequency with which a normal cholecystographic response was obtained in the presence of symptoms that were interpreted as being due to gallbladder disease by competent internists. It seems rather unusual that in the presence of so-called gallbladder symptoms only twenty-two pathologic responses were obtained radiographically in these ninety-five cases, all of which had been carefully worked up clinically. Three patients failed to retain the dye for fifteen minutes and the lack of filling was not considered sufficient evidence to warrant a diagnosis of nonfunction. These patients refused further examination.

It is not my intention to try to prove the superiority of cholecystography over the time proved clinical examination but rather to correlate all the observations and determine whether they are in accord or at variance as regards the clinical changes presented by the patient. I was prompted to undertake this investigation because of some rather embarrassing operative results that followed the reports of pathologic gallbladders after one cholecystographic examination. The operation was usually performed a month or so following the radiographic examination. I do not mention this interval between the radiographic examination and the operation as an alibi, it did, however, furnish food for thought. The following reasoning was pursued. First, was it not possible that the gallbladder or the cystic duct was inflamed during the time at which a negative radiographic response was obtained and later the inflammation and edema either in the gallbladder or in the cystic ducts had subsided and at the time of operation the gallbladder appeared normal and the surgeon thought it inadvisable to remove it? One might even go further and in the presence of edema in the cystic duct obtain a nonfilling gallbladder, and at operation with removal of the gallbladder the pathologic report would show a normal gallbladder. It is well known that inflammation in other parts of the body, namely, the ostea of the accessory sinuses of the face and head, inflamed during acute infections, obstruct drainage and later return to normal. It is my belief that the same fact can be rightfully applied to the gallbladder or cystic duct. With these points in mind I thought that it would be advisable and important to investigate all nonfilling gallbladders and subject the patient to at least a second examination after a period of a month before stating whether or not the gallbladder was functioning.

It was my object when this work was undertaken to obtain 100 nonfilling gallbladders. After the 100 were obtained it was my intention to place fifty of the patients on a normal diet as controls and fifty on a gallbladder diet, rich in fats, with the addition of dehydrocholic acid. I am reporting only the cases in this series in which the gallbladder diet plus the dehydrocholic acid were used. The management which was carried out as a routine measure on the patients varied according to the individual but consisted essentially of frequent feedings made up of as much milk, cream, butter and eggs as the patients could tolerate, plus pureed vegetables and pureed fruits. Most patients were fed every hour or two. In addition to the foregoing, most of the patients were on antispasmodics and dehydrocholic acid. The dosage of dehydrocholic acid was $3\frac{3}{4}$ grains (0.25 Gm.) three times a day with meals.

Any one familiar with cholecystographic examinations is aware of the emptying power inherent in fats such as milk, cream and yolk of eggs. Many investigators have proved conclusively that small stones in the gallbladder have been expelled after the patient has been on a diet rich in fats. I believe that it is possible to have a small stone in the neck of the gallbladder or the cystic duct, and obtain a nonfilling gallbladder. In the same patient after the ingestion of foods rich in fat it is not uncommon at the second examination to procure a normal cholecystographic response. The presence of multiple stones in the gallbladder which can be definitely outlined does not militate against the possibility of a normal functioning gallbladder radiographically. This fact has been proved by many investigators and in this series there are a number of patients showing multiple stones in the gallbladder who on repeated cholecystographic examinations showed a normal response. It is not my intention, however, to intimate that the majority of gallbladders containing stones function normally. This observation has been made repeatedly. A patient with a nonfunctioning gallbladder will frequently show multiple soft stones after a month's interval, having been on milk, cream, egg yolks and dehydrocholic acid.

While I have not reached my goal, owing to lack of time and to the difficulty in obtaining patients with gallbladder symptoms who show a negative response, I believe that the facts obtained are at least worthy of some consideration. Although the number of patients that I have had has been limited and far below my expectation I do not hesitate to make this statement. A patient with fairly typical gallbladder syndrome following one negative gallbladder response does not conclude the necessity for immediate operative intervention as the patient frequently will show a normal cholecystographic response at a later examination. Before any patient is subjected to surgery he or she should be reexamined radiographically after an interval of one month or, even better, reexamined after an interval of a month with the patient having been on a diet rich in fats during the intervening period. Many writers emphasize the importance of the presence or absence of stones as an indication for operation, therefore a second examination may be helpful in establishing these facts.

Another rather interesting observation in this series of cases was the bizarre symptomatology in patients who showed a negative cholecystographic response. Some of these patients had only vague symptoms referable to the gallbladder, their chief complaints

being generalized abdominal distress, constipation and irritable bowel. Many were tender on palpation over the colon and in the epigastrium. The clinical course of many of these patients seems to parallel quite accurately the cholecystographic response, that is, taking a patient with symptoms attributed to gallbladder disease followed by a negative cholecystographic response, there was usually a marked improvement of the symptoms following medical management including dehydrocholic acid. Likewise the cholecystographic response at this time was either improved or normal. These same patients who frequently showed an exacerbation of symptoms and were immediately subjected to cholecystographic examination usually showed a poorly functioning or a nonfunctioning gallbladder. From these observations it would appear that, in the absence of stones, proper medical management favorably influences the symptomatology of the patient, and the function of the gallbladder is correspondingly improved radiographically. A few patients showed no improvement after a rather prolonged medical regimen and likewise showed no improvement in the radiographic gallbladder appearance. Owing to the fact that the gallbladder could not be visualized in these patients it was impossible to state whether or not stones in the gallbladder were responsible for the nonfilling or possibly the gallbladder and cystic duct were incorporated in a mass of adhesions. Unfortunately, from a statistical point of view, none of these patients have as yet been subjected to surgery.

For a matter of convenience and clarification, I have divided the series of ninety-five cases into eight classes:

- 1 Normal responses, seventy. Eighteen were rechecked.
- 2 Pathologic response followed by a normal response, eight.
- 3 Stones in the gallbladder, with normal responses on two or more examinations, two.
- 4 Stones in the gallbladder with poor responses, four.
- 5 No dye in the gallbladder on two or more examinations, five.
- 6 Normal response followed by nonfilling one.
- 7 Unsatisfactory responses, patient vomited dye, did not cooperate, three.
- 8 Variable responses, that is, responses would be normal one time, poor the next, normal, poor, two.

The oral method of examination was used in this series. One would infer that the oral ingestion of the dye is very satisfactory, as only three of the patients in this series were unable to retain it for a sufficient period of time which was felt to be necessary for its absorption. I have also made the deduction that, if a patient will retain the dye for one-half hour or longer, enough will be absorbed to give a satisfactory shadow in the presence of a normal functioning gallbladder. This statement is made in view of the fact that a number of patients vomited a half hour after the oral administration of the dye, and the gallbladder cast a normal radiographic shadow.

CONCLUSIONS

- 1 In this series a large percentage of the patients with symptoms referable to the gallbladder gave normal cholecystographic responses. Seventy patients of the total of ninety-five, or 73 per cent, showed a normal functioning gallbladder.
- 2 Eight, or 40 per cent of the twenty patients with nonfunctioning gallbladders showed a normal response radiographically after medical management.
- 3 Of the twenty patients, five or 25 per cent showed a negative cholecystographic response on two or more occasions even after medical management.

4 From past experience substantiated by the results of this series, one negative cholecystographic response is not an indication for immediate operative intervention even in the presence of gallbladder symptoms. I believe that more than one negative radiographic examination is necessary before the patient should be subjected to surgery. The presence of gallstones is probably the most important indication at this time for surgical intervention. Cholecystography after a gallbladder regimen will often clarify this important query.

1439 South Michigan Avenue.

CAUSES OF BLINDNESS IN PENNSYLVANIA

FROM THE MEDICAL AND SOCIAL ASPECTS

ALFRED COWAN, MD

State Supervising Examiner for Pensions for the Blind
AND

S MERVYN SINCLAIR, BA

Executive Director, Pennsylvania State Council for the Blind
PHILADELPHIA

Unfortunately, in the various state acts relating to blind persons there is such a wide variation in the definition of blindness and in the procedure by which the blindness of an individual is determined that it has been extremely difficult, if not impossible, to gather together data of such a nature that they can be studied on the basis of any uniform standard.

In an effort to overcome this difficulty and to establish a uniform definition of blindness and classification of the causes of blindness, there was organized some years ago a Committee on Statistics, a body composed of representatives of the American Foundation for the Blind, the National Society for the Prevention of Blindness, the American Association of Workers for the Blind and the Statistical Committee of the Section on Ophthalmology of the American Medical Association. Out of the deliberations of this committee have come certain recommendations and suggestions which, if generally adopted, will give a uniformity of statistics on blindness that has not heretofore been available.

The enactment of legislation in Pennsylvania for blind relief, very shortly after the recommendations of the Committee on Uniform Statistics had been made public, presented an opportunity for putting these recommendations into effect on a large scale.

The Pennsylvania blind relief law, while conforming in many respects to similar laws in other states, differs from all the others on three major points—the method of its administration, the procedure to be followed in determining the causes of blindness and the definition of blindness.

In Pennsylvania there has been for more than twenty years an established organization for the administration of the Mother's Assistance Fund, known in some states as Widow's Aid. This fund is administered by county boards of trustees who serve without pay. It is supervised by the parent organization in the state welfare department. Social welfare programs are carried on by qualified paid workers. When acts were passed for relief for the blind and for assistance to the aged, it was wisely provided that responsibility for their administration should also be placed in the hands of these

already efficiently functioning boards. This method of administration has served as a model for many other public health and social welfare programs in Pennsylvania and other states.

The method decentralizes relief and brings blind recipients in close touch with the agents of the state who distribute the grants. It makes possible certain other social services, services that a small pension cannot provide but which most individuals and their families need. The person who needs teaching or is employable is brought to the attention of the agency skilled in teaching the blind or to employment officers, who are often able to find work for the capable. Health problems of the pensioner and his family are referred to the family physician, if there is one, and otherwise to the organization best equipped to deal with them. But probably the most valuable factor in administering relief through the Mother's Assistance Fund is the opportunity it affords to protect family contacts against unnecessary eye hazards. Social workers taught to organize a sound social hygiene program and trained to recognize deviations from the normal eye conditions can secure for their wards the medical care and continued treatment which are often the sole means of preventing blindness.

The regulations of the act require every applicant to submit himself to an accredited ophthalmologist for examination and they further provide that the ophthalmologic reports pass through the hands of a supervising ophthalmologist attached to the staff of the department of welfare. This makes possible a uniformity of judgment and diagnoses which can be secured in no other way. Of all the other states having blind relief laws, Missouri alone provides for a similar procedure.

These provisions have made available for study and analysis what is probably the largest single series of reasonably descriptive reports of blind eyes up to the present time. It is estimated that they represent about 50 per cent of all the blind in the state, and from the data contained there can be deduced, with a fair degree of accuracy, the relative percentages of the various ophthalmic diseases which are the sole or main contributing cause of blindness, the underlying etiologic factors, the distribution of the blind throughout the state, and the predominance of the various causes and their relation to the prevailing occupations in the locality found, the relation of prevalence of blindness in certain localities to accessibility to competent medical assistance, blindness due to ignorance, carelessness or poverty, blindness due to traumatism, accidents to the good eye of one-eyed persons, heredity, and so on. While we intend to elicit eventually much information of value from both the medical and the social aspects, the present communication is limited to a more or less general survey and classification of the various causes of blindness.

At the outset it is only fair to state that the final analysis must be faulty to a certain extent. It should be considered that the applicants, in most instances, submitted themselves for examination long after all activity of the primary disease had subsided—in the majority of cases many years after—and sometimes with one or two empty sockets. The examining physician seeing a person for the first time, with no case record of the disease before him, is compelled to base his diagnosis on the appearance of the eye at the time of examination and to the frequently faulty history by the patient himself. It should be considered also that much of the substance of the reports necessarily depends on the

Valuable help was rendered by Mrs. Bernice English of the Council for the Blind, State of Pennsylvania.
Read before the Section on Ophthalmology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

answers of elderly, ignorant or otherwise unreliable patients, or even intelligent ones with a tendency to distort facts

The reviewer, with or without reason, was often made to feel that the given diagnosis was not always correct and thus because of no fault of the examiner. For example, such diagnoses as congenital microphthalmus or congenitally undeveloped globes might easily be the sequelae of ophthalmia neonatorum. One report, illustrating the extreme difficulty of eliciting information from the patient, stated "Eye enucleated. No injury. Pathology not known." Many other examples might be mentioned. The primary disease given was

often, therefore, mere conjecture and it is fortunate that the act makes it a requirement that the examining physician must be an accredited ophthalmologist, one whose opinion is of value.

While the causes of blindness as given in the series as a whole are reasonably reliable, the same cannot be said with regard to the underlying etiologic factors, which are given in table 1. Even with all our modern facilities an underlying etiologic factor often cannot be found much less in these examinations, in which it was almost always necessary to obtain the information from the applicant himself. Every clinician knows how a patient will associate one disease with another or with some accident which might or might not be material. The supervising examiner has taken the liberty of rejecting a number of given etiologic factors such as when for example, influenza, eyestrain or diseased

tonsils was given as the cause of senile cataract. It could be plainly seen that often an examiner had thoughtlessly jotted down the patient's statement. But whenever a reasonable underlying cause was given it was accepted as positive, even though the examiner himself had expressed a doubt.

The tabulation is of the eyes of those who, with visual acuity of less than 3/60 or 10/200 with both eyes, were defined as blind persons according to the original act. In the last act, approved July 9, 1935, one with visual acuity of 3/60 or 10/200 or less was defined as a blind person.

In order to serve the purpose of this report best and to avoid overlapping, one diagnosis only, the primary disease which was considered to be the main cause of blindness, was chosen from the data. Complications, sequelae and secondary disorders are not mentioned. Also, because in so many instances the cause of blindness was found to differ in the two eyes of one individual, eyes and not persons are enumerated.

In arranging the various diseases into the twelve groups comprising the present classification, some explanation is in order. The compilation of such a large number of reports by so many physicians made it necessary, of course, to condense terms and to modify them to a considerable extent in many instances.

Those cases of congenital anomalies the report of which indicates more than one disease entity are grouped under "defective globes." These include also such notations as underdevelopment or malformations. Classified under penetrating wound of the globe are included not only those reported as penetrating wounds but also intra-ocular foreign bodies, adherent leukoma, gunshot wounds, eyes lost in explosions, and other injuries vaguely described but resulting in the loss of an eye.

Such diagnoses as iritis, iridocyclitis, kerato-iritis, plastic iritis, cyclitis and complicated cataract are placed under the heading of uveitis. This group includes all disorders of the uveal tract except when there was a definite diagnosis of choroiditis or the description warranted, but even some of these are grouped under uveitis if, in addition, there were other changes noted such as complicated cataracts. Chorioretinitis, retino-choroiditis and chorioretinal atrophy are all grouped under choroiditis.

It is considered permissible to include among senile cataracts all those diagnosed as diabetic in which the lenses became opaque after the age of 50 years, although a notation is made of the associated diabetes. Needless to state, in numerous instances in which the cause of blindness is given as senile cataract there was a previously existing retrolenticular condition that could not be determined. This can be inferred from the numerous absolutely blind persons with senile cataract. All nontraumatic intra-ocular lesions due primarily to vascular disease such as hemorrhages and exudates in the retina, embolism, thrombosis, proliferans, angio-sclerosis and so on, are included under vascular retinitis.

All those diagnoses such as retinochoroiditis, choro-retinitis and optic neuritis which resulted in optic atrophy, and also those cases which were designated as secondary optic atrophy or optic neuritis without notation of any other lesions, are classified as neuro-retinitis.

It will be seen that the most frequent cause of blindness in this tabulation is senile cataract, 22.49 per cent. Of the total number of these eyes, 2,666, 1,927 were

not operated on for various reasons—through neglect, unwillingness or other reasons on the part of the patient, or because of poor operative risk. The remainder, 706 eyes, were failures, either because of postoperative complications or of some previously existing retrolental lesion. This is certainly a small proportion of the great number of cataract operations performed.

Traumatism is next in importance as a cause of blindness, 14.68 per cent. This percentage of blindness due to trauma is no indication of the great number of individual eyes lost through accident. For the past fifteen years approximately 450 eyes each year have been lost by industrial accidents and in no year has there been more than twenty double eye accidents.

Glaucoma of the adult type occurred in 13.34 per cent of all cases. Of the total number, 768 were operated on, at least 120 received inadequate treatment, as indicated in the reports, and 204 received no treatment whatever.

Uveitis, with a percentage of 12.63, is extremely high when it is considered that choroiditis and the traumatic and postoperative disorders of the uvea are not included in this group.

Simple optic atrophy ranks next, with about 10 per cent of the total.

TABLE 2—*Given Etiologic Factors Other Than Traumatism, Senility and Congenital Anomalies*

| | | | |
|-------------------|-----|------------------------|-----|
| | 17 | Scarlet fever | 50 |
| | 2 | Tuberculosis | 20 |

| Arthritis | 5 | Brain tumor | 105 |
| Pregnancy | 14 | Other tumors | 4 |
| Sinusitis | 4 | Typhoid | 14 |
| Influenza | 41 | Consanguinity | 2 |
| Smallpox | 8 | Encephalitis | 6 |

The percentage of ophthalmia neonatorum, 3.9, ranks lower than congenital anomalies, with 4.48 per cent.

In general it will not be possible to apply these causes of blindness universally throughout the United States. This can readily be understood from the wide variation in causes of blindness and the percentages, when the total figures for the whole state are broken down into counties. These differences appear to bear a distinct relationship to the industries predominant in the community, the racial and other characteristics of the population, the facilities for adequate care and the general understanding of the need for such care in the early stages of any eye disease. For instance, through those sections of Pennsylvania in which mining is the predominant industry, a high percentage of the blind population have lost their sight as a result of explosion accidents which have at one time destroyed both eyes. In certain other areas which are extremely rural and in which there is little or nothing in the way of specialized medical service, large percentages of the blind have lost their sight from causes which would or might have yielded to prompt treatment in the early stages, and also such conditions that could have been corrected by operation. Again, such diseases as trachoma, which

is the most common cause of blindness in certain states, is extremely rare as a cause of blindness in Pennsylvania.

Table 2 must be considered of questionable value both from the standpoint of the actual underlying etiologic factor as has been explained, and also with regard to the number. For example, probably most of the 470 cases of ophthalmia neonatorum were gonococcal infections, yet gonorrhea is given as the underlying cause of the loss of only seventeen eyes. The same may be said of syphilis with relation to interstitial keratitis. On the other hand, the numbers seventy-two, fifty and forty-one for meningitis, scarlet fever and influenza, respectively, are undoubtedly exaggerations.

1930 Chestnut Street

ABSTRACT OF DISCUSSION

DR. E. V. L. BROWN, Chicago. The payment of goodly sums of money to the blind in the shape of pensions has again added to our knowledge of conditions which cause blindness this time in an industrial and mining state, Pennsylvania. The only previous highly valuable report was from an agricultural state, Missouri. The unusual significance of these two reports is due to the fact that the laws in these states require an examination of the eyes by an accredited eye doctor. Three other states namely, Colorado, Idaho and Oklahoma and the District of Columbia now require examination by an eye doctor but no reports concerning the causes of blindness found in these states have appeared, so far as I can learn. In Pennsylvania the information obtained by the local eye doctor is passed on by a state supervising examiner, at present Dr. Cowan. Dr. Cowan has wisely edited, i. e., interpreted, the reports thus furnished him and arranged and classified them according to diseases and etiologic factors. He estimates that the report covers about half of the actual number of blind in the state. If the roughly 12,000 eyes thus reported on come from 6,000 individuals this would make around 12,000 blind in the state. This 12,000 figure, when put alongside the 1930 federal census figure of 4,373 blind in Pennsylvania demonstrates how effective a money inducement is in bringing out an otherwise undisclosed condition. The Missouri law did much the same thing. In these increasingly accurate statistics, some well known and some heretofore less well determined facts stand out. For instance, senile cataract was the diagnosis in 22 per cent of those who became blind in Pennsylvania. Trauma caused 15 per cent of the blindness. Seventeen per cent for uveal disease is surprisingly high. Four per cent for ophthalmia neonatorum shows what advance prevention work is making. Glaucoma rates high with 13 per cent congenital anomalies run 5 per cent. Dr. Cowan first excludes trauma and congenital anomalies. He then excludes "senility" as a cause but does not state just what he means by senility as a cause of blindness. This might well include the 22.5 per cent caused by senile cataract, and then the three—trauma, congenital anomalies and senile cataract—would add up to 42 per cent. However, the long list of forty other etiologic factors determinable applies to only 1,898, or 16 per cent of the 11,852. This 16 per cent with known etiology plus the 42 per cent excluded with known etiology makes 58 per cent in which the cause of blindness in Pennsylvania may be considered to be known. But there are an equal number in the state who are not pensioned. We are therefore confronted with the startling fact that, in what is undoubtedly the best report our country has so far been able to produce with a very large number of eyes, 12,000, all examined by eye doctors, one of the older states of the country has to admit that the cause of blindness is unknown in nearly three fourths of the cases. It is highly desirable first that other states follow and that more reports on the diseases in these eyes and the causes be made.

DR. WILLIAM H. CRISP, Denver. The problem of furnishing financial and other help for the blind is by no means simple. The need for a definition of blindness arises largely out of the need for a standard on which to base the assignment of charity to those who because of loss of sight are prevented from gaining their livelihood. The standard of blindness, from

the economic point of view, is actually bound to vary with the individual case. A former patient of mine with vision of about 20/240 or less than 10 per cent of normal, was successful in profitably raising young plants that were bought by the farmers in his neighborhood. Yet another man with better vision than this will be quite unable to earn a living. Technically, my old gardener had 100 per cent loss of industrial vision as measured by the standard adopted by the industrial commission of the state of Colorado. The patient's mental and moral equipment play an extremely important part in the problem, and the kind of work he attempts to do and to which his mentality can adapt itself is also extremely important. In some telephone services there are very efficient blind operators engaged in special services. The rules for provision of pensions to the blind, of course, make allowance for this phase of the problem. Statistics have been multiplied seemingly without end. Yet often the information afforded is far from reliable. Statistics are useful only as a basis for future action. Information about the blind in Pennsylvania is useful, as indicated by Dr. Cowan, as a basis for provision of various social services to the blind, including care of their general health, facilities for education and training, and opportunities for employment. Statistics have also an educational and prophylactic value in dealing with the general public. Unfortunately, some unreliable features of the information obtainable can never be altogether remedied because of remoteness of the time when loss of vision occurred, lack of technical records, and often inaccuracy in technical records because of carelessness or ignorance on the part of the general physician. Some causes of blindness seem rather hopelessly beyond control. Among these is the miscalculated dynamite explosion, from which so many of Dr. Cowan's miners lost both eyes. The attempt to remedy the condition of these patients is usually very discouraging, but it is often worth making if some sight remains in at least one eye.

DR. CONRAD BERENS, New York. Dr. Cowan should be congratulated on his careful study of 6,000 cases which is almost double the number we reported on before this section last year. The group studied by our Committee on Statistics of the Blind is a fairly accurate cross section of students in schools for the blind in the United States. Our observations agree quite closely in certain respects with Dr. Cowan's statistics. Our figures in regard to the hereditary and congenital causes of blindness are naturally much higher (51 per cent) because our studies were concerned principally with young children. These studies clearly indicate the need for treating this group with greater intelligence. More thorough examinations and more carefully prepared records of the initial examinations of these cases will aid materially in obtaining the necessary statistical data regarding etiology. Possibly the examination and treatment of these cases are better organized and more thorough in Pennsylvania than they are in many other states, for Dr. Cowan's statistics do not show quite so clearly, as do the national statistics, the great need for improved methods in diagnosis and treatment. We found many children in these schools for the blind who should never have been admitted and many who could have been released had they received proper treatment. On behalf of the Committee on Statistics of the Blind, I again urge the continued cooperation of every ophthalmologist in this work. Initial examinations must be more thorough and records more complete if the data which our committee is assembling are to be valuable in directing programs for the prevention of blindness and for research in the etiology of diseases that result in blindness. Additional studies similar to those made by Dr. Cowan and by our committee are needed to maintain interest in these problems.

DR. ALFRED COWAN, Philadelphia. What I have said is the result of analysis of the data collected in the first year after the enactment of the law. There are twice this number of reports to consider by now. This first report lacks a certain value for this reason. When the law was enacted and administration begun there came at once a group of applicants for pensions composed of persons who had been blind for a number of years up to seventy, eighty and ninety. Data of this kind, of course, are not nearly so valuable as they will be in the future years. In the future the reports of more recently

blinded persons will be available. I do not think that the etiologic factors given here are of much value. The causes given are those recorded on the reports by the examining physicians. In many of these cases senile cataract was given as the diagnosis, when I know for a certainty, without having the privilege of writing it down, that there were some other conditions long before the cataract developed. Under a law in which the examiner is an accredited ophthalmologist, we shall have real data. This was to be a model law, and in the first draft it was required that the ophthalmologist be certificated by the board of ophthalmic examiners. That is in the act, but there was added "or one legally allowed to practice ophthalmology." In other words, they just emasculated that part of the act which we should like to retain as a qualification for the man who makes the examination. I think it would be fine if some thing could be done in that respect in future acts.

CINCHOPHEN—IS THERE A SAFE METHOD OF ADMINISTRATION?

WALTER LINCOLN PALMER, MD
AND
PAUL S. WOODALL, MD
CHICAGO

In this paper we shall attempt to answer the question "Can cinchophen be given safely if given carefully?" The question itself implies that cinchophen is a dangerous drug.

Cinchophen, phenylcinchoninic acid, seems to have been discovered in 1887 by Doebner and Gieseke¹ and to have been introduced into medicine under the trade name of atophan in 1908 by Nicolaier and Dohrn. Since that time it has been used extensively for gout as well as for other forms of arthritis and for the relief of pain of all types. In 1932 Hench² listed thirty-two drugs known to contain cinchophen or its derivatives as the active constituent and stated that he had accumulated the names of 500 remedies advertised in American drug lists as cures for rheumatism or as uric acid solvents, many of which undoubtedly possess cinchophen as the base. It has been estimated by White³ that the annual consumption of cinchophen and its derivatives in the United States is about 90,000 pounds.

No serious effects were noted from cinchophen until 1913, when Phillips⁴ described certain skin reactions as indicative of an idiosyncrasy to the drug. In 1922 Schroeder⁵ called further attention to its toxic effects. The first case of jaundice attributed to cinchophen was reported in 1923 by Worster-Drought⁶ and the first fatal case with jaundice two years later by Richard Cabot⁷. In the decade that has elapsed, an increasing

number have been reported. In 1930 Rabinowitz⁹ was able to collect fifty cases. In 1933 Weir and Comfort¹⁰ gathered together 117 cases, the mortality rate being 51 per cent. At the present time we are able to bring the total number of cases of jaundice following the administration of cinchophen or its derivatives to 191.

Snyder and his associates,¹¹ however, have reported recently the routine treatment of 2,500 cases of chronic arthritis with cinchophen over a ten year period without a single case of liver damage. These authors feel "that the fatal cases of acute yellow atrophy of the liver attributed to cinchophen were either coincidences or in some way were due to lack of control in administration of the drug." Eaton¹² has treated several thousand patients with cinchophen intravenously and has never seen a case of jaundice following its administration. Snyder and his associates hazard the assumption that "if all cinchophen administration were stopped immediately, acute yellow atrophy would still go on in the general population at the same rate." Lehman and Hanzlik¹³ also reject most of the clinical evidence on the ground that it "is distinguished by the *post hoc ergo propter hoc* type of reasoning." They conclude further that cinchophen toxicosis lacks an adequate experimental basis, especially as regards injury to the liver. It is necessary for us to take issue with these views, for we believe that there is adequate evidence, both clinical and experimental, of the definite toxic effect of cinchophen on the liver.

In 1913 Biberfeld¹⁴ reported that he had observed the death of one dog from severe degeneration of the liver after the administration of two 5 Gm doses of atophan with an interval of several days between the doses. Churchill and Van Wagoner¹⁵ in 1931 reported that after the administration of cinchophen to dogs the liver, on microscopic examination, "showed varying degrees of liver necrosis from small areas of coagulation necrosis just beneath the capsule—to complete disappearance of liver cells in small areas." One year later Myers and Goodman¹⁶ found definite evidence of liver damage in both dogs and rabbits following the ingestion of cinchophen. In 1933 Barbour and Fisk¹⁷ examined the livers of dogs that had received the drug and reported "widespread necrosis with little of the normal architecture of the organ preserved" and stated that "the injury produced by each of these drugs (i.e., cinchophen, tolysin and sodium salicylate) was as definite as that caused by such well known liver poisons as phosphorus and chloroform." These workers therefore seem to have obtained definite experimental evidence of the hepatotoxic action of cinchophen and its derivatives.

It is, of course, obvious that the vast majority of patients are able to take cinchophen over long periods of time without apparent injury. The nature of the peculiar hypersusceptibility that results in the occa-

sional case of jaundice and death is obscure. Our purpose in this paper, however, is to review the reported cases in an effort to ascertain, if possible, what relationship exists between dosage and toxicity and whether or not cinchophen can be given safely if given cautiously. The Council on Pharmacy and Chemistry has suggested that "physicians should be educated in the use of this dangerous drug, as in the case of other dangerous drugs." This implies that there is a proper and an improper method of administration. We have reviewed the literature with this one question in mind: Can cinchophen be given safely if given carefully?

It should be recalled that the pharmacopoeial dose of cinchophen is 0.5 Gm, or 8 grains. Sollmann¹⁸ states that "the usual dosage is 0.5 to 1.0 Gm four times per day" and advises that it be "stopped with the first appearance of gastro-intestinal disturbance, skin rashes or jaundice." Short and Bauer¹⁹ consider the usual dosage to be from 1.5 to 3 Gm a day and state that between 10 and 13 Gm is necessary for the

TABLE 2—Mortality Reported Cases of Jaundice Following Administration of Cinchophen or Its Derivatives

| Method of Administration | Death | Recovery | Total |
|-------------------------------|------------|-------------|------------|

| Total | | | 191 |

complete therapeutic effect. Graham²⁰ advises that the drug be given for four days and then withheld for four days. The dose of neocinchophen, according to Sollmann, is the same as that of cinchophen. Neocinchophen has been considered nontoxic, its limited solubility precluding the possibility of toxicity.

Table 1 summarizes all the published and unpublished reports of cases that we have been able to find to date. A number of points are of interest as one studies this table, especially the variable relationship between total dosage and outcome. Small doses have often caused death, whereas large amounts have frequently not proved fatal. It is significant that discontinuance of the drug with the appearance of vague symptoms of jaundice has not sufficed to prevent a lethal termination in the majority of fatal cases. Another important point, not shown in the table, is the "time factor," to which Sir William Willcox²¹ first

directed attention—that is, the variable length of time between the use of the drug and the first appearance of symptoms—a delayed effect such as is seen in chloroform poisoning. The initial symptoms have frequently appeared weeks or months after the discontinuance of the drug. Death may not occur until long after the period of cinchophen administration. In many of these patients the destructive processes in the liver appear to be irreversible, for in spite of treatment they progress to death in nearly half of the victims.

Table 2 gives a comparison of the mortality rate with the different methods of administration in this total group of 191 cases. It is noteworthy that the death rate from the oral administration was about 48 per cent, from the intravenous method 27 per cent, and from the combined oral and intravenous administration 25 per cent. This might be considered to suggest that the intravenous method is safer than the oral. We are inclined to attribute the difference, however, to the small number of cases in the intravenous group and to a small total dose of cinchophen. The total number of cases, 191, with eighty-eight known deaths and a mortality rate of 46.8 per cent, is significant. Many authors have suggested that the actual incidence of cinchophen poisoning is much greater than the reported cases would indicate. We are in accord with this view.²²

The accompanying chart shows the age distribution of the reported cases by decades. It may be noted that the peak occurs between the ages of 40 and 70. It is noteworthy, however, that two cases occurred in the second decade and sixteen in the third. It seems probable, therefore, that susceptibility is not a matter of age. The higher incidence after the age of 40 is probably to be attributed to the greater use of cinchophen, for

It will be seen from table 3 that cases occurred following cinchophen administration in a great variety of conditions, practically all of them painful and including six cases of gout.

Table 4 illustrates the late or delayed manifestations of liver damage following continued cinchophen administration. In the first case a standard dose of the drug was taken daily for six months. No symptoms appeared until three weeks before death. In the second case the same dosage was taken for eight weeks

Two weeks after the administration of cinchophen jaundice appeared, followed in five weeks by death. The third case is of particular interest, for this patient had used cinchophen in large doses for three years without apparent ill effects until suddenly jaundice appeared, and death resulted in ten or twelve days. The fourth case is significant because a very small amount of neocinchophen was taken for only three weeks, and because an interval of nine and a half months elapsed before death occurred. In the fifth case the dosage was moderate, and death did not occur until five months after the drug had been discontinued. It is noteworthy that the procedure followed in the third case was that recommended by Graham, i. e., three or four days of drug administration followed by a four day rest period. Graham was trying to find a "safe" method of administration.

These five cases are of great interest in connection with the method of action of cinchophen, for they indicate that the necrosis of the liver is not an allergic manifestation but rather an abnormal susceptibility. From the standpoint of dosage, method and carefulness of administration, however, the significant facts are, first, that three of these patients were able to take the drug for long periods of time without symptoms, second, that fulminating acute yellow atrophy did eventuate, and, third, that in two of the cases an interval of several months elapsed between discontinuance of the drug and death.

In table 5 the effect of neocinchophen is shown. It has been thought by many that neocinchophen because of its lessened solubility, is not toxic. These seven patients, however, are reported to have taken neocinchophen only, and yet five of them died—a mortality rate of 71.4 per cent. Tolysin and novotophan are trade names for neocinchophen. The fourth, sixth and seventh cases are of particular interest because of the small doses that proved fatal.

TABLE 4—Chronic Dosage—Late Effects

| Case No. (Author) | Drug | Dosage | Result | Liver at Autopsy |
|---------------------------------------|---------------|--|--|--|
| 34 (Lowenthal, Mackay, Lowe) | Atophan | 1.5 Gm daily for 6 mos | Death 3 wks after onset of symptoms | Acute toxic necrosis (538 Gm) |
| 35 (Lowenthal, Mackay, Lowe) | Atophan | 0.5 Gm t i d 3 days per week for 8 wks * | Death stopped cinchophen 2 wks before onset of jaun- dice 5 wks before death | Acute toxic necrosis (744 Gm) |
| 45 (Relchle) | Cinchophen | 205 Gm in 1926 157 Gm in 1927 117 Gm in 1928 | Death after jaundice of only 10-12 days duration | Acute toxic necrosis (757 Gm) |
| 168 (Bloch, Rosenberg) | Neocinchophen | 0.5 Gm t i d for 3 wks | Death 9½ mos after drug had been stopped | Toxic cirrhosis (1 000 Gm) |
| 169 (Bloch, Rosenberg) | Farastan | 0.5-1.0 Gm t i d at intervals for 18 mos | Death did not take drug within 5 mos of death | Toxic cirrhosis (1 200 Gm) gastric ulcer |

* Drug prescribed in manner suggested by Graham, i. e., not over four days in succession with an interval of four days.

the common types of chronic pain are encountered more frequently during these years.

The sex distribution does not seem to be important. There were 110 females (60.4 per cent) and seventy-two (39.6 per cent) males in the 182 cases in which the age was stated.

22 Palmer, W. L., Woodall, P. S., and Wang, K. C. Cinchophen and Toxic Necrosis of the Liver—A Survey of the Problem. *Tr. A. Am. Physicians*, 1936, to be published.

Table 6 illustrates the disastrous results that may follow the ingestion of very small doses for brief periods. In the first case the patient took only 15 grains (1 Gm) a day for one week. No symptoms appeared until three weeks later, and death occurred a month later. In the third case 30 grains (2 Gm) was taken daily for two days only, the first symptoms appeared fifteen weeks later, and death resulted after three or four more weeks. In the fourth case 15 grains was given daily for fifteen days while the patient was in the hospital, there were no symptoms until two weeks later at home, death occurred twenty-two days later. The fifth case is especially significant. Seven and a half grains (0.5 Gm) of cinchophen was given each night for five nights. The patient was instructed by her physician to stop the drug if any gastro-intestinal disturbance developed. She did so five days later when she reported to her physician with slight jaundice, but the necrosis of the liver steadily progressed to death thirty-one days later.

These five cases, to our minds, proved conclusively that even the smallest doses of cinchophen given for very brief periods may prove fatal. They also show clearly the futility of relying on close observation and withdrawal of the drug with the first appearance of symptoms. It is then usually too late, for the disease marches steadily forward.

It is apparent that cinchophen is not a drug like digitalis or ergot or emetine, which is toxic only in large doses and which, when used in small doses, gives adequate warning of toxicity. It is, on the contrary, a drug that may be fatally toxic even in very small doses. The necrotic changes in the liver may progress to death even when the first symptoms do not appear until several weeks or months after the administration of cinchophen. The very earliest symptoms may be only a signal, already too late, that the steady march of death has begun.

Instances have been cited in which the long continued use of cinchophen has been without apparent harm until the sudden appearance of jaundice followed by dramatic death. In some cases the administration of very small doses of the drug under careful observation with immediate withdrawal on the first evi-

TABLE 6—*Small Doses—Acute Effects*

| Case No (Author) | Drug | Dosage | Result | Liver at Autopsy |
|------------------|------------|---|--|---|
| 64 (Walker) | Cinchophen | 64 Gm in 1 wk. | First symptoms appeared 5 wks after stopping drug; death occurred 11 days later | Acute toxic necrosis (8.0 Gm) |
| 73 (Willcox) | Atophan | 0.3 Gm t i d for 8 days July 10 to 18 | First symptoms Aug 8 died Sept 5 | Not mentioned typical symptoms of acute necrosis of liver |
| 97 (Rhea) | Cinchophen | 2.0 Gm daily for 2 days | First symptoms appeared 15 wks after ingestion of drug; died 3-4 wks later | Acute toxic necrosis (978 Gm) gastric ulcer |
| 109 (Winfield) | Cinchophen | 10 Gm daily for 15 days while in hospital | First symptoms appeared 2 wks later at home; death resulted in 22 days | Refused |
| 162 (Fraser) | Cinchophen | 0.5 Gm q noc for 5 days; advised to stop if gastro-intestinal disturbance developed | Reported to physician 5 days later with slight jaundice; cinchophen stopped; death followed in 31 days | Acute toxic necrosis (1,050 Gm) |

dence of toxicity has nevertheless proved fatal. It is therefore concluded that there is no safe method for the administration of cinchophen.

ABSTRACT OF DISCUSSION

DR. MANDRED W. COMFORT, Rochester, Minn.: The authors' answer to their question "Is there a safe method of administering cinchophen?" is irrefutable. There is no safe method of administering cinchophen. Regardless of the precautions taken, occasional instances of cinchophen poisoning will occur. I do not believe that the reported cases of toxic cirrhosis following the use of cinchophen include anywhere near all the instances of poisoning. There are undoubtedly hundreds of unreported cases throughout the world. Fifteen cases encountered at the clinic since 1933 are unrecorded as yet. The morbidity and mortality following the use of cinchophen must be reduced to a minimum. This can best be accomplished by (1) governmental limitation, so that it is dispensed and administered only on prescription of physicians, and (2) by members of the medical profession limiting the indications for its use. The danger of cinchophen poisoning is so real that we believe at the clinic that the drug should not be used when there is an effective substitute, but since there is no effective substitute in the treatment of gout, we concur in the belief of our colleague Dr. Hench that its intermittent use is justifiable "in cases of gout not only during the attacks of gouty arthritis but in the intervals thereafter in order to prevent the next attack and to ward off, if possible, the much more important residual and potentially fatal lesions in the cardiovascular system." We do not use it in any other disease. Until these steps are taken, mortality and morbidity can be reduced it seems to me, in at least three ways. 1. Use of the drug should be discontinued when the first manifestation of toxicity appears. In five, or 15 per cent, of the cases which we encountered use of the drug was continued for from one to two weeks after toxic symptoms had appeared or the drug had been repeatedly taken again and again after repeated warnings. One of these patients died. I agree with the authors that poisoning will occur in spite of this precaution. 2. The danger of taking further cinchophen

TABLE 5—*Neocinchophen Only*

| Case No (Author) | Drug | Dosage | Outcome | Liver at Autopsy |
|---------------------------------|---------------|---|----------|--------------------------|
| 60 (Ross) | Tolysin | Unknown dose intermittently for 2 mos. | Death | Acute toxic necrosis |
| 69 (Ross) | Tolysin | Irregularly for 2-3 wks probably not over 8 Gm in all | Recovery | |
| 95 (MacGregor) | Neocinchophen | 0.3 Gm t i d Rx refilled several times | Death | No necropsy |
| 106 (Davis) | Tolysin | 0.63 Gm 4 times daily for 19 days | Death | No necropsy |
| 163 (Bloch and Rosenberg) | Novatophan | 17.5 Gm in 1 mo | Recovery | |
| 167 (Bloch and Rosenberg) | Novatophan | 7.7 Gm in 3 mos occasionally 0.15 Gm thereafter | Death | Subacute toxic cirrhosis |
| 168 (Bloch and Rosenberg) | Neocinchophen | 0.5 Gm t i d for 3 wks total (31.5 Gm) | Death | Toxic cirrhosis |
| 7 cases—mortality 71.4 per cent | | | | |

SUMMARY AND CONCLUSION

In the past decade there have been described 191 cases of jaundice following the administration of cinchophen or its derivatives, including neocinchophen. Of these, eighty-eight ended fatally, a mortality rate of 46.3 per cent. The actual incidence of this sequence is undoubtedly much higher than the published reports

should be impressed on the patient who has recovered from cinchophen poisoning. Two of our patients took more cinchophen after being warned, and they died. 3 Surgical procedures should be avoided. Of the sixty-one fatal cases reviewed by Weir and me, in eight, or 13 per cent, the patients died following surgical procedures. Operative procedures on patients who have toxic cirrhosis attributable to cinchophen are almost always fatal. A review of such cases leaves little doubt that the lives of these persons could have been saved, or their illness prevented, had these precautions been taken.

DR D R CLIMENKO, Cold Spring Harbor, N Y. I do not believe that the phenylcinchoninic acid derivatives are hepatotoxic substances in the ordinary meaning of the term. When one speaks of a hepatotoxic substance, such as chloroform or phosphorus, one means a substance that will always produce a certain type of tissue damage, and that the damage which will be produced will be proportional to the amount of the noxious substance that has been administered. This is obviously not true in the case of cinchophen, as the authors themselves have pointed out. Acute yellow atrophy has occurred after the administration of extremely small quantities of the drug, on the other hand, Dr Hensch has described at least two cases in which individuals have taken as much as 50 pounds of the drug over a period of years without any definite deleterious action. In my own animal experimental work I have only been able to corroborate Hanzlik's results. In a series of animals that has now extended to over 200 rabbits and forty dogs, oral administration of either cinchophen or neocinchophen, in doses up to and including 1,200 mg per kilogram (that is, a dose of 1,200 grains, or 78 Gm, for the average sized adult) has shown no hepatotoxic action. My second point has to do with the frequency of toxicity from cinchophen in man. There is no reasonable doubt in my mind that cases of acute yellow atrophy have occurred in man as a result of the administration of cinchophen. I feel equally certain that a large number of the cases so described in the literature have other etiologic agents present that might equally well be responsible for the terminal condition. For example, I should like to describe more fully the case the authors quoted, the case described by Reah in the *Lancet*, Sept 3, 1932, of a man who died fifteen weeks after the administration of 4 Gm of cinchophen. Fifteen weeks after the administration the man was admitted to the hospital suffering from acute abdominal distress and jaundice. Sixteen days after the onset of acute symptoms he died. Post-mortem examination showed the presence of a peptic ulcer, endarteritis and toxic cirrhosis. The clinical history described him as a chronic alcoholic. Nor is this an isolated case, for I have collected some twenty similar ones. One of the best is a case described by Dr Rake of London. A man was admitted to the hospital with jaundice and an acute abdominal condition. Laparotomy was performed under chloroform anesthesia. The man died three days later. Post-mortem examination showed a chronic cirrhotic liver on which was superimposed an acute degenerative process. The clinical history describes the patient as a chronic alcoholic. Yet the death is described as one of cinchophen poisoning.

DR R GARFIELD SNYDER, New York. The authors have tried to prove that there is no safe method of administering cinchophen but they have provided only circumstantial evidence to substantiate their claims. The fact that acute yellow atrophy occurred in a few isolated cases in which cinchophen had been administered prior to the onset of jaundice does not in any way prove that death in these cases was due to the use of cinchophen. It may merely have been a coincidence, as the number of cases of acute yellow atrophy reported from unknown causes far exceeds the number of cases reported as being due to the use of cinchophen. It is therefore obvious that on the clinical evidence alone it is not justifiable to state that cinchophen has ever caused acute yellow atrophy. It is true that cinchophen salts can be recovered from the liver in cases in which death occurred from acute yellow atrophy. The finding of cinchophen derivatives in the liver however does not necessarily prove that they caused liver damage because cinchophen is normally excreted through the liver. From a pathologic standpoint the gross and microscopic appearance of the liver in cases supposedly due to cinchophen poisoning does not in any way differ from the gross and microscopic appearance

of the liver in cases in which acute yellow atrophy developed from unknown causes. In regard to experimental evidence, most authors cite the work of Barbour and Fisk (*J Pharmacol & Exper Therap* 48 341 [July] 1933) as proving the toxicity of cinchophen for the liver cell. As a matter of fact, subsequent to Hanzlik's questioning of this work Barbour and Gilman (*J Pharmacol & Exper Therap* 55 400 [Dec] 1933) tried to duplicate their results and absolutely failed. There is at present no technique known for the production of acute yellow atrophy in animals by cinchophen. From a clinical point of view my associates and I have been using cinchophen for a period of ten years in our private practices and in the clinic of the Hospital for Ruptured and Crippled and Roosevelt Hospital without ever having a fatal result. In all my experience I have seen only one slight case of jaundice, which lasted two weeks. It cleared up completely and did not in any way interfere with the patient's general health or the successful treatment of the case.

DR CHAUNCEY D LEAKE, San Francisco. Practical ideas on the toxicity of the cinchophens are necessarily inferior when derived experimentally from animals, no matter how carefully controlled, in comparison with similar notions obtained from its clinical use in man. The reason is a statistical one, since relatively few animals can be employed whereas hundreds of thousands of human beings take the drugs. Physicians are concerned with avoiding an untoward reaction in any single patient. An excellent survey of the chances of obtaining an unfavorable reaction to a drug in a large series of individuals has been made by A J Clark (*Tr Med-Chir Soc. Edinburgh, in Edinburgh M J*, January 1935). In using any drug a physician must balance the hazard of its use against the disease hazard in his patient. There is always some therapeutic hazard. The wise physician will strive to keep this at a minimum. In regard to the cinchophens, clinical evidence indicates that neocinchophen is less hazardous to use than cinchophen.

DR WALTER L PALMER, Chicago. I wish to second what the chairman has said with regard to the commercial interest involved. It is enormous. It comes, if I am correct, from one source.

DR LEAKE. We all happen to know that source, unfortunately, it is not to the credit of the company.

DR PALMER. I was interested in what Dr Comfort said with regard to the role of surgical procedures. We have noted such a relationship in one or two of our own cases and it is described frequently in the literature. Apparently the anesthetic, even an ether anesthesia, adds enough additional damage to the liver to initiate the appearance of symptoms or at least make them worse. With regard to gout, I find myself again at odds with some of my colleagues. I do not treat very much gout but my associates in Chicago who treat some very bad cases tell me they are able to handle these patients satisfactorily over a period of years without cinchophen. With regard to the question raised by Dr Climenko about the relation between dosage and toxicity, I admit readily that there is not that definite relationship one likes to see between cause and effect but this I believe is explained by assuming a hypersusceptibility the cause and nature of which are entirely obscure. I would like to tell of an experiment of Dr Sutton's. Dr Sutton gave a patient cinchophen for one week and jaundice appeared. Several weeks later the patient asked for cinchophen and he was given 1 grain (0.065 Gm) daily for three days. Nothing happened and so the dose was increased to 2 grains (0.13 Gm) daily for two days, a total of 7 grains (0.46 Gm) in five days. Jaundice appeared, the patient became acutely ill but eventually recovered. To my mind this observation possesses the quality of the crucial laboratory experiment. With regard to the question Dr Snyder raised as to whether or not these cases of acute yellow atrophy may be due to unknown causes or to the cinchophen, I feel that cinchophen in these instances is of unknown cause. We know that acute toxic necrosis of the liver is a toxic process. The microscopic picture is the same in the poisoning of the liver from chloroform, phosphorus, trinitrotoluene and numerous other substances. Wilson in England wrote an excellent article on this subject in which he listed a large number of hepatotoxic compounds. I feel that cinchophen is very definitely one of these drugs.

VOLUNTARY FOOD HABITS OF
NORMAL CHILDRENCLIFFORD SWEET, M.D.
OAKLAND, CALIF

During the past fifteen or more years I have been urging parents in my office and in public addresses to allow their children full choice of both kinds and amounts of food from the family table. When this advice has been followed from infancy no food difficulties have arisen, but when other tactics have been followed and reeducation of both parents and child must be undertaken a period of observation and detailed report is valuable and usually necessary.

This discussion will differ from others on the subject with which I am acquainted because it is based entirely on experience gained in private practice with children living in the home with their parents, while other writers have recorded the behavior of children in institutional groups.¹ Also the foods offered after infancy have been those that appear usually on the average well stocked family table without restriction as to mixtures or the free use of sugar, such as Davis used in her earlier classic studies.² I have emphasized the child's complete freedom of choice more strongly than Aldrich³ has in his delightful and thoroughly sound book on cultivating the child's appetite. A period, usually three weeks, during which, while free from all restraint, the child's behavior is carefully recorded and reported, has been found to be an excellent means of winning the cooperation of parents and of gaining accurate information concerning the food habits of the entire family. This method of study I have not seen reported. Finally, I believe that the practices and methods which the physician finds useful in his daily contact with patients should be more frequently presented in professional meetings and periodicals in order that they may, when sound, become more generally used and, subjected to criticism and modification, grow inevitably toward perfection, which is the ideal of medicine.

My daily experience indicates that a great number of mothers are still "getting food into their children." Too many colleagues are advising them that certain foods must be taken regularly or are paying so little attention to this aspect of child training that the mother is left adrift to follow her own devices, modified by the constant bombardment of sales propaganda for milk, cereals, vegetables and less worthy foods to which she is subjected. During the past ten years I cannot recall a resident or intern in the Children's Hospital who, in response to my question "What will you tell the mother when she tells you her child will not eat?" has not answered "I don't know, but I suppose I'd tell her to make him eat the food he should have." Evidently in their minds food was to be prescribed and given as were drugs, baths and enemata.

In all fairness, I must hasten to add that I am certain that the medical profession is not altogether to blame for the conduct of parents concerning the food intake of their children. The desire to feed some one is an inseparable part of the maternal instinct, and the belief (the stock in trade of quacks) that there is some method of feeding which, if followed closely, will prevent many if not all the ills of human beings dies hard. When I advised the mother of a boy of 6 years not to urge or coax him to eat she said "Oh yes, our doctor has cared for him since he was born and he has always told me that, and I've read Dr. Aldrich's book on 'Cultivating the Child's Appetite' which has helped me a great deal, but we still coax him to eat." That evening his father had staged a race with him in order to get him to gulp down his dinner, all to no avail because he had vomited it at midnight in the course of an acute infection.

Most mothers whom I see, except those who have been carefully trained to do otherwise, worry because their children do not eat satisfactorily. Rarely is the answer to my question "has he a good appetite?" an unconditional "yes." Usually the reply is "No, it is very poor," or "I can't get him to eat vegetables," or "He doesn't like meat," or "I just can't get milk down him" or "He eats an egg only when I force him." At best a favorable reply is modified by "Fairly good except vegetables" or "I guess it is all right, but he doesn't eat enough to satisfy me." And I am certain that modern mothers still pray "Oh! dear Lord, I beseech Thee Wilt Thou not make my children fat and me thin?"

When questioned concerning the methods used to get a meal down which satisfies parental anxiety, the reply indicates coaxing or entertainment to take his mind off his food, so that eating may become largely passive, the application of sporadic and ineffectual force interspersed with prolonged and oft repeated lectures on the great values of certain foods, especially vegetables. (I am quite certain that the average California child can't easily spell vegetable because the letters f-i-g-h-t come up out of his subconscious mind to confuse him.)

Usually the offensive is carried on alternately by one parent or the other, while the one whose turn it is to rest silently or openly sides with the culprit. When the child happens to be hungry or the food especially suits his taste and he eats a big meal the parents fairly flap their wings and crow "good child, you have eaten your dinner," and then the child fully realizes how valuable his mealtime behavior is as a weapon.

Here is the soil that will nourish any and every sort of behavior problem to thrive in an atmosphere of faulty family relationships.⁴ In the face of such a situation we might well pause and ask ourselves, for what are we profited if we shall bring up a perfectly nourished generation, handicapped from its earliest days in the development of those qualities of the spirit which alone make life beautiful?

Fortunately this is not an unsolvable problem since every healthy child will eat an adequate diet⁵ if it is provided for him and if his food education is carried on along reasonably sound pedagogic lines.

The young mother must be taught that the formula prescribed for her infant is made sufficient to allow him all the food he wants and that it should be offered at prescribed intervals. When additional foods are prescribed they should be given in small amounts, and if they are resisted a taste for them should be taught gradually. Human nature has always yielded more readily to seduction than to violence.

Few mothers realize that the components of a balanced diet need not all be eaten every day. They must be assured that a commonly taken and necessary food should be omitted without opposition for days whenever the child tires of it, the child's body has abundant stored up supplies to draw on during the holiday, and when he needs the food he will take it gladly.

E. J., a girl, aged 11 months, was brought to me because she was refusing milk, although she was taking vegetables, cereals, orange juice, cod liver oil and eggs readily. The mother was instructed to omit all milk until the baby showed signs of wanting it. After she had frantically telephoned me many times to report that the baby still didn't show signs of wanting milk, I asked her to place a bottle where the child could see it and await results. Finally, on the eleventh day the child nearly scrambled off a table in an attempt to reach the bottle. Earlier in practice I would have offered that baby every known concoction of milk and would have failed in the end.

Children who are allowed to omit a food at will do not develop a lasting dislike for it as they do when it is forced on them against their will. When mothers are taught to substitute "he has not yet learned" for "won't," there will seldom be lasting difficulty in cultivating a taste for new foods. Many persons do not like such delectable foods as celery, grapefruit and olives when they first taste them, and might I mention tea, coffee, tobacco and beer?

Intervals between meals should be varied to fit the needs of the individual. Some very young infants who do not eat well and whose food doesn't agree with them will thrive on a five hour schedule.

M. B., a very unhappy infant of 4 months, who cried night and day, spat up continuously and was troubled with an allergic dermatitis, became a happy infant with a clear skin who gained 9 ounces (256 Gm.) the first week after she was on a five hour schedule.

Often after a few days on a five hour schedule the infant will voluntarily return to the four hour interval and should be allowed to do so. Regularity will enable the mother to give her child better care, but she must not become the servant of regularity.

H. M., at the age of 7 years was brought in by his mother in despair because she could not get him to eat. When I asked her to let him choose his own diet she was loath to do it and was certain that I should either give him a tonic or give her some new way to whip him into line. I finally won her cooperation by asking her to follow my advice for three weeks, keeping a careful record of his food intake, unknown to him. He began at once to take an ample diet but omitted the mudday meal. He is now 15 years of age an unusually large muscular athletic boy who still eats morning and evening only. Incidentally when I reviewed his record as an infant I found that he omitted his night feedings very early and took only three meals a day much earlier than most infants do.

C. A., born July 24, 1935 with a birth weight of 7 pounds 2 ounces (3,233 Gm.) was seen December 3 at the age of 4 months referred by a colleague in another city with the following note: Began vomiting at 10 days. At 1 month given two weeks trial on atropine and thick feeding. Then operated to find a fusiform cartilaginous thickening in the first portion of the duodenum, forming a complete constriction. Course subsequently favorable except dislikes food and vomits daily about one half of food given.

On admission the weight was 13 pounds 4 ounces (6,010 Gm.). The child was brought in because it had lost 9 ounces (256 Gm.) and during the past two weeks was unable to retain food. It was forced to eat, a meal often lasting from one to two hours with the father carrying on after the mother became exhausted. It had been fed every three hours. It had a violent distaste for milk and was put on orange juice, ripe banana, cereal with butter and sugar, and apple sauce. The orange juice was given ad lib and other food at five hour intervals.

December 4 the report states "Can't get a thing into her except orange juice." The mother was advised not to force food.

December 10 the weight was 12 pounds 11 ounces (5,745 Gm.), a loss of another 9 ounces in six days, but the mother was encouraged because the child was now taking meals well and cried when food was taken away. It was put on a white milk mixture with lactose, orange juice, cod liver oil and iron ammonium citrate, 50 per cent solution, 15 drops daily to correct moderate anemia.

December 24 the weight was 13 pounds 8 ounces (6,123 Gm.) a gain of 13 ounces (370 Gm.) in fourteen days. It was taking 7 ounces at a feeding, at times as much as 10 ounces without regurgitation. The bowel movements were too hard to pass easily. Lactose was partially replaced by Vitavose. Vegetables were prescribed to be given twice daily. The baby was taking all food well and was in good condition.

Jan. 7, 1936, the weight was 14 pounds 3 ounces (6,435 Gm.) a gain of 11 ounces (313 Gm.) in fourteen days. The baby was eating well. A mild allergic dermatitis had appeared on the face and body. The bowel movements were normal. It was in excellent condition.

February 4 the rash was worse. Evaporated milk was ordered in place of fresh pasteurized milk, and barley flour instead of Pablum.

March 3 the weight was 15 pounds 12 ounces (7,144 Gm.), a gain of 10 ounces (284.5 Gm.) in twenty-eight days. The baby had an acute infection of the upper respiratory tract. It was noted that the rash was made worse by tomato juice. The mother was giving the barley flour uncooked as she had the Pablum. She was instructed to put the baby in a sleeping bag so that she could sleep with both eyes closed at night.

March 30 the weight was 17 pounds (7,711 Gm.) a gain of 18 ounces (510 Gm.) in twenty-seven days. It was sleeping soundly and had taken as much as 13 ounces at a feeding without discomfort or vomiting. It was on a five hour schedule, taking 10 or 12 ounces morning and night. At the other two meals it took vegetables and 5 or 6 ounces of milk mixture. The skin was clear. There were normal bowel movements. The baby was in excellent condition. A happy mother and infant.

Malnutrition has been overemphasized until it has become a menace to the peace of mind of mother. The slender child with excellent turgor and development for his age is labeled underweight by comparison with standard height, weight and age tables too frequently. Physicians can be of great service by carefully studying such children, reassuring the anxious mother and giving her a written statement that she may use in future discussions of the subject.

Forced feeding has its place in medical practice but when used it should be a therapeutic measure carried out under specific orders to accomplish a definite purpose.

The first step in the solution of any problem is a clear understanding of the problem to be solved. This is especially true of behavior problems, which have in them so many variables of heredity and unknowns of environment. Therefore, if it can be done without harm to the child, he should for a time be allowed to direct his own behavior while the parents become only observers and confidential informants. At the end of the observation period the problem has either disappeared or has lost enough variables and unknowns to fall within the means of fairly simple solution. When the food problems of older children present themselves I ask for a period of three weeks in which the child

may choose his own food as a guest at the family table while I am forwarded a weekly report of his food intake. Usually before the weeks have elapsed the child is eating a varied diet, and I often have difficulty in getting the third week's report because the mother has lost interest in the problem.

At the end of the observation period one has gained a good working knowledge of the foods that make up the family diet, which is otherwise difficult to obtain in private practice. This furnishes a basis for constructive criticism if it is needed and for sound teaching of such fundamental dietetics as

1 For practical purposes one vegetable is as good as another, that, after all, a carrot is only a root vegetable, while spinach is only one of many leafy ones. That raw vegetables, which many children prefer, may wholly or in part supplant cooked ones with no loss except the energy which the more complete digestion of cooked food makes available, and that this loss has no importance in a diet which contains such energy producing foods as meat, fish, eggs and milk, that vegetables should be cooked in the least possible amount of water and no water discarded,^{1c} that having eaten a large vegetable salad, the child need not then eat the vegetables served in the course, or that a mealtime, other than breakfast, or for that matter days spent without a morsel of vegetable passing the lips is not altogether lost if only the child does not come to cry out with those wandering children of old, "my soul abhorreth" vegetable.

2 That meat is a valuable food for which fish is the only complete substitute, while broth has no value except as a vehicle for other foods, and that cheese adds nothing to the diet except milk content.

3 That cereals served in the much advertised form of hot mushes do not gain any values not present in them when served as bread, as crackers or as ready to eat, packaged dry cereal, preferably sufficiently "whole grain" to retain their vitamin B complex. The time honored hot cereal is cooked on top of the stove, bread is at least as thoroughly cooked in the oven, while the dry cereals are generally more thoroughly cooked than either.

4 That not every child needs a quart of milk daily and that he should be given credit for the milk he takes with other food as well as that drunk.

5 That a diet too high in fat not only decreases appetite but prevents digestion, absorption and consequently growth, therefore cream should not be used too freely and cod liver oil should be given in the amounts and forms prescribed by the child's physician.

6 That temporary loss of appetite may mean nothing except that the child is not hungry, while a more prolonged absence usually is the first symptom of illness and the most dependable symptom of the need for a careful physical examination.

7 And especially that the father's duty is only to earn the money to buy food and the mother's to put it in suitable variety and form on the table.

Very frequently, after keeping a written record for a short time, the mother is surprised to find that the child is eating much more than she had thought and is convinced that her child's voluntary intake is sufficient. Also the period of three weeks has been found sufficient for the child to indulge in and recover from any orgies that he may indulge in with his first taste of freedom. For example during the first few days desserts and other foods high in sugar may be eaten to excess, but the child soon returns to the other foods,

often omitting dessert for days at a time.^{2a} Any child may at times eat a peculiar meal, often having periodic recurrence of the desire to limit his diet for a meal or two to some particular food. If this does not occur too often or last too long, and my own conviction is that it will do neither, it should pass unnoticed.

D S., a large well nourished boy who was a very bad eater earlier in his life but now takes a very satisfactory diet, makes a meal on bread and milk about five or six times a year, no matter what other foods may be on the table. At first it was very difficult to persuade his mother to remain calm while he ignored the excellent dinner she had been at much pains to plan and prepare, to eat with evident enjoyment "baby food" as she called it.

Often, though not invariably, the child will voluntarily omit the food to which he is hypersensitive. With this omission anorexia, irritability, constipation or manifest allergic signs and symptoms may quickly disappear. The withdrawal of foods to which the child is hypersensitive often has a magic effect on appetite and disposition. The strict interdiction of all foods from his diet which the child says "I do not like" for a few days or weeks often changes at least the greater number of them to the highly desirable list for which he will then ask. This is a splendid example of negativism of which Aldrich³ writes. Recently I saw a boy of 8 years who had always resisted milk. Forty-eight hours after milk was removed from his diet he asked "Doctor may I please have some milk on my cereal?"

Also at the end of the observation period whatever faulty food habits the child has are clearly apparent and the parents can then be instructed to carry out definite steps in the process of reeducation. If the child takes too much milk, certain meals, preferably dinner, can be given without milk or the milk may appear only as dessert. However, parents must be warned not to hold any food up as a bribe. The child who is said not to like meat seldom dislikes it but has not learned to chew it sufficiently to swallow it, so after accumulating a ball of several partially chewed pieces removes them from his mouth. Within a few days he can be taught to eat meat if it is given to him in single small pieces and no more is given until the first has been chewed and swallowed.

I am certain that no normal healthy child can long resist the demands of his body for food when there is added to it the example of the other members of his family eating the food that appears on the table or omitting it without remark in an atmosphere of comradeship and enjoyment. He soon learns that the tastes of one member of the family cannot be too constantly consulted in planning meals and this lesson may form the very foundation stone for the building of a happy and generous personality, resting firmly on the realization that in all mutual human relationships he must give thought to others as well as to himself.

CONCLUSION

1 Too many parents are still carrying on an ineffectual and harmful struggle with their children in order to "get in" a complete diet.

2 Physicians must not only prescribe diets but carefully instruct parents in methods of carrying out the child's food education.

3 Healthy children, if allowed to do so, will voluntarily choose an adequate diet from a well supplied family table.

ABSTRACT OF DISCUSSION

DR. W. C. C. COLE, Detroit The physician can rarely find any physical basis for anorexia. It is seldom a matter of dietetics or nutrition. The problem is usually one of conflict between the child and his environment. The failure to eat well is either a protest against too rigid regulation of the child's diet or is a weapon used in keeping the parent under control. Obviously, juggling the diet or the giving of various combinations of vitamins or the administration of so-called tonics can accomplish nothing. A great deal has been learned about the physiology of nutrition, but the psychology of feeding has been largely neglected. It has been learned that certain foods are very desirable in the human diet and that a proper balance is important to a satisfactory state of nutrition, but little has been learned about getting children to take willingly the foods which it is thought they should have. As a result, the benefits that should be derived from improved knowledge have to a considerable degree been offset by an increase in the psychologic problems associated with eating. Perhaps attempts have been made to regulate the child's eating habits too closely. Much consideration is given to the composition of the food but little attention is paid to its appearance, variety or palatability. Many babies now receive most of their food from cans the contents of which can be identified only by referring to the label. The mother gets the impression from physicians, from magazine articles, from the various government bulletins and particularly from the high pressure advertising of those who sell foods that if she fails to get the specified things into her child as directed he surely will not be well. Individual tastes and peculiarities are seldom taken into consideration and the child is expected to fit into the mold that has been built for him. If he has normal human reactions, he soon objects to such regulation and offers strenuous resistance. The more he resists, the more the mother urges. The child almost invariably wins and the problem of anorexia is well begun. By the end of the second year it has become a fixed habit. It is striking that the problem is seldom seen in large families or the lower social groups, where the mother is too busy or lacking in education to give her child scientific attention. As lowly an animal as the guinea-pig will voluntarily select a balanced diet if it is available and if he is left to his own discretion. Yet we insist on rigidly regulating what and when our babies eat. It is apparent that if we are to control the problem of chronic anorexia we must respect the child's individuality and approach the question from a sound psychologic point of view. Dr. Sweet is to be highly commended for bringing this vital subject before us and for giving us the benefit of his experience and observation.

DR. J. D. BOLD, Iowa City Certain groups of children rarely present feeding problems. Noteworthy examples are the inmates of orphanages and children required to follow a strictly prescribed dietary because of disease. Health surveys of the children in better types of orphanages and of children receiving wisely chosen therapeutic diets show a better level of nutrition than is observed in the average child in the public school. These facts indicate that feeding problems encountered in private practice depend on something other than the child. Most pediatricians will grant that the parents primarily are at fault. I am not convinced that there is any one type of treatment that can be recommended for meeting these problems. We shouldn't direct our attention to the child when it is the parent that is the chief offender. Since the earliest time there have been self-choice diets. That is the type of diet management that has always existed and with that there have been varying degrees of subnormal nutrition. With the dietary practices that are common among adults and children in this country, a child cannot be expected to choose an adequate diet from the foods that are commonly placed before him. The foods commonly used are inadequate for the best nutrition. The child in choosing his own diet, can be expected to choose only something poorer than the total of the foods that are offered to him. Before self-choice diets can be recommended as a desirable form of management our national food habits must be markedly improved. The problem is primarily one of educating parents and children in the physiology of normal nutrition. It is one of giving to the child the initiative in as large a measure as possible and from the earliest practicable moment.

This is in agreement with the plan of self-choice diets. It is one of directing the child's habits through intelligent persuasion on the part of the parents. Lastly, the practice should be one of avoiding making the child's habit control an avenue or outlet for the parent's emotional unrest and maladjustment.

DR. CLIFFORD SWEET, Oakland, Calif. I hoped I might get some good, healthy objections here so I could act as a child does when some one tries to force him to eat—resist. I have gotten no serious disagreement, except that apparently Dr. Boyd is not quite so ready as I am to trust the child to choose his own food. I think that Dr. Boyd and I are not in disagreement, because I mean to take the emphasis off what the child eats and place it on teaching parents to make available to the child what he should eat, and to allow him, especially when he is not hungry, to omit his food at will until he is ready to take it. In more than fifteen years of following this practice, when I have been able to win the mothers to the plan of letting their infants take as much or as little food as they want from the beginning, there has been no difficulty whatever. I have failed to make this plan work many times because I couldn't get the cooperation of the parents. This morning the mother of one of my former patients in Oakland was calling me up to tell me that her baby is still not eating. She said "I try your plan sometimes but then I go back again." Every time a parent starts to educate the child in one direction and, before she gets very far, weakens and goes back to the old way, the problem is multiplied many times. I wish that pediatricians would try this plan of letting the child eat as he pleases for a while and see what he eats. Then at least the problem will have clarified itself in a short time and they will know whether there is anything to correct, and what they have to do in order to correct it.

POSTPRANDIAL INSULIN

INDIVIDUALIZING TIME OF ADMINISTRATION
OF INSULIN

MILTON PLOTZ, M.D.

Acting Associate Visiting Physician Kings County Hospital
(Long Island College of Medicine Division)

BROOKLYN

Recent progress in the treatment of diabetes mellitus has done much to increase the life expectancy and happiness of the patient. It has also increased and complicated the difficulties and responsibilities of the physician, who now, besides watching diet, urines and blood sugars must decide whether or not to give insulin, whether to use the common brands of insulin or a new, more slowly acting insulin, when to give the injections, how much to prescribe and how to prevent and treat reactions. He must guard against undue optimism on his own part and on the part of the patient, who often regards insulin as a diabetic panacea and forgets that diabetic complications are more frequent than before and that hypoglycemic reactions and "sugar spills" are still to be reckoned with. It has been the aim of this study to emphasize certain of these problems in the management of the diabetic patient and to indicate ways of individualizing the patient.

It is now generally recognized that a safe and effective time for the administration of insulin is before meals since "the maximum effect of an injection of insulin occurs in an hour, in contradistinction to that of the peak effect of food on the blood sugar which takes place in half that time. Neither statement is absolute, the latter particularly is subject to variation. It is not so well known that in selected cases it may

Read before the Section on Pharmacology and Therapeutics at the
Eighty-Seventh Annual Session of the American Medical Association,
Kansas City, Mo., May 15, 1936.
1. Joslin, F. P. Therapeutic Applications of Insulin. J. A. M. A.
105: 359 (Aug. 3) 1935.

be even safer and more convenient to vary the insulin schedule with relation to food intake. The level of blood dextrose is subject to diurnal fluctuations quite independent of the ingestion of food, and it is important that maximum insulin action coincide with the more elevated levels. Jacob Mollerstrom,² following the work of Forsgren, has emphasized the rhythmic nature of glycogen metabolism in the liver and has pleaded for the administration of insulin with due regard for endogenous rhythm as well as for meal hours. That this would be the ideal method of treating the diabetic patient cannot be denied, but it is expensive and in many cases an impractical method for large hospitals and private practices, since it requires numerous blood analyses and prolonged observation of the patient in a carefully controlled environment.

FRACTIONAL URINES

To facilitate the study of a diabetic patient it is wise to examine the urine several times a day. This method of evaluation of diabetic status is in use in diabetic services throughout the country, but, since it has still not been generally adopted by practitioners at large and is an important aid in individualizing the patient, the method used at the Kings County Hospital during this study will be discussed briefly at this point. Each day four specimens are collected, measured and analyzed:

- 1 All urine passed from bedtime to breakfast
- 2 All urine passed from breakfast to lunch
- 3 All urine passed from lunch to dinner
- 4 All urine passed from dinner to bedtime

More or fewer specimens may be taken to meet certain contingencies or the times of collection may be varied to suit the doctor, but the principle of dividing the daily urine for fractional examination has demonstrated its value and should be more widely used, especially by those who do not have elaborate laboratory facilities. The food intake, especially the available carbohydrate, being known, it is easier to prevent glycosuria than when twenty-four hour or casual urines alone are taken.

At the Kings County Hospital during the study, it was found convenient to divide the diet as prescribed by the physician into three meals containing approximately equal portions of fat, carbohydrate and protein and to adjust only the insulin dosage unless the total daily number of grams of one of the foodstuffs was to be changed. In private practice using fractional methods it is easy to vary both the amount of food and the insulin at frequent intervals, depending on the amount and time of the glycosuria and the convenience of the patient, such as working hours.

REPORT OF CASE

A patient on a diet of 150 Gm of carbohydrate and 90 Gm each of protein and fat (carbohydrate 150, protein 90, fat 90, calories 1,770) received 50 Gm of carbohydrate and 30 each of protein and fat at each meal. During twenty-four hours, receiving 10 units of insulin before each meal he passed 1,200 cc. of urine containing 2 per cent dextrose, or a total loss of 24 Gm a day. Instead of reducing the amount of carbohydrate ingested or increasing the amount of insulin fractional urines were taken, showing that specimens 2 and 3 contained no dextrose and that all the dextrose was passed between dinner and breakfast. With this lead and by more careful study of the patient's glycosuria after dinner, it was found that by giving finally 5 units before breakfast and 15 units after dinner, there was no longer glycosuria, the total amount of insulin taken and the diet remaining the same.

² Mollerstrom Jacob. Periodicity of Carbohydrate Metabolism and Rhythmic Functioning of the Liver. Arch. Int. Med. 52: 649 (Nov.) 1933.

CLINICAL INVESTIGATION OF POSTPRANDIAL INSULIN

In an effort to learn whether reactions would occur more often with the routine administration of insulin after meals than with the conventional schedule, the patients of the female diabetic inpatient department of the Kings County Hospital were given insulin immediately after meals every other day. On alternate days the patients were given insulin as usual before eating and the number of reactions (insulin shocks severe enough to be recognized by patient or nurse) was carefully noted. A note was also made of the number of "spills," that is, the presence of dextrose in one of the fractional urines. The diet and insulin dosage were kept constant in each case. There were 1,052 insulin injections in the first (postprandial) series, and 1,055 in the second. There were eleven reactions (1.05 per cent) in the first series and ten (0.95 per cent) in the

Reactions and 'Spills'

| | Number of Injections | Percentage of Reactions | Percentage of Spills |
|--------------|-------------------------|----------------------------|-------------------------|
| After meals | 1 052 | 1 05 | 2 1 |
| Before meals | 1 055 | 0 95 | 1 9 |

second. There were twenty-two "spills" in the first series and twenty in the second. As can readily be seen, there was almost no difference in the number of reactions and in the number of "spills" in these unselected series, nor were there any complaints from the patients.

It is essential not to misunderstand the purpose of this experiment. The results are not quoted to support a program of routine postprandial insulin. This would obviously be as wrong as any other inflexible schedule and probably less justifiable physiologically than the method now in common use. The experiment does however show that postprandial insulin administration is safe and feasible and should be considered in cases which present difficulties in diabetic management. As many observers have demonstrated, it is sometimes necessary to give insulin at unusual hours, before, after and between meals, and even late at night. It has even been found desirable occasionally to have one dose given as late as between midnight and breakfast.

There are definite indications for considering a change in insulin schedule for the diabetic patient.

1 Any patient who cannot be kept free from shocks on his present regimen should be carefully studied from the point of view of his insulin timing.

2 Patients with gastro-intestinal upsets will often require insulin after meals. Tuberculous or post-operative patients, for example, who are vomiting may be kept free from shocks if the dosage of insulin is regulated according to the amount of food the patient has actually ingested and kept down rather than according to a theoretical diet which he may refuse to eat or may be lost by emesis.

If the present trend toward allowing diabetic patients greater freedom in their diets continues, radical changes in hospital routines may ensue. This is especially true if it is followed to the extremes (still foreign to American ideas) suggested by Adolf Lichtenstein³ of Stockholm, who following the lead of Stolte of Breslau, permits diabetic children to eat what they wish as long as there is satisfactory weight gain and no

³ Lichtenstein Adolf. Nord med tidskr. 35: 1329 (Aug. 31) 1935. See comments in Lancet 2: 1068 (Nov. 9) 1935.

acidosis Here it may be wise to give insulin after seeing what the patient has actually eaten, not according to what he may eat

Under certain circumstances an intelligent diabetic patient may elect to postpone his usual dose of insulin. Such a situation sometimes arises when he may have to eat away from home, for example at a public function, where he cannot predict or change the menu. In such a case many diabetic patients can quickly estimate the amount of insulin which they need and take it after the meal.

Situations sometimes arise in which the conventional insulin schedule has had unpredictable disastrous results. This was rather dramatically shown in an experience of Dr. Greene's,⁴ in which a patient, after administering 25 units of insulin, found that she missed one of the ingredients of the meal. She went to her grocery shop and on the way engaged in conversation with a neighbor, delaying long enough to go into severe shock and coma. I have also seen an epidemic of shock in a hospital ward when the elevator bringing the food broke down. These examples are not given so much to condemn giving insulin before meals as to illustrate that when it is given in this way the cooperation of an intelligent patient or staff is necessary.⁵

CONCLUSIONS

1 It is urged that the insulin schedule be carefully studied in order to individualize the patient. This will necessitate giving insulin usually before but sometimes after meals or at odd times.

2 With the use of newer, more slowly acting, insulins, either alone or in combination with a rapidly acting insulin, the necessity for close study of the time of insulin administration will be increased.

3 Insulin should be given with regard to the actual food intake of the patient rather than in relation to a theoretical diet. This is especially true with relation to tuberculous or postoperative patients, children, or those with capricious appetites or vomiting.

4 Fractional examination of the urine is more desirable in the study of the diabetic patient than twenty-four hour specimens.

5 In a large series of injections it was found that the number of shocks and the incidence of glycosuria was approximately the same whether insulin was given before or after meals.

ABSTRACT OF DISCUSSION

DR. RALPH H. MAJOR, Kansas City, Mo. When those of us who are interested in insulin first began to treat patients with this new and powerful therapeutic method we followed a routine of giving the patient his insulin half an hour before meals and wondered at first why some patients got along so well and others did so badly. Further observations showed clearly that in many instances there was an apparently more rapid absorption of insulin than in others. Up to the present time there has been no way of estimating the rapidity of this absorption except by studying the individual patients and examining either the urine in separate specimens or by making repeated blood sugar examinations. I have found the repeated blood sugar examinations preferable but there are serious objections to carrying them out in outside practice. I wholeheartedly subscribe to the idea emphasized by Dr. Plotz that the estimation of the urine along with the gain in weight and general condition is by far the most important laboratory procedure. I have been much interested in several patients I have

seen recently who showed very high blood sugars following their meals and an hour later went into insulin shock. These patients had been getting insulin in the customary fashion, a dose half an hour before meals, but careful study of their blood sugar showed that they apparently had a very slow absorption of insulin, the peak not coming before two and one-half or three or on some occasions four hours, with the result that the patient's blood sugar went up quite high following the meal. He spilled over sugar and then the insulin began to get in its effect and he had a shock a short time after showing a large amount of sugar in the urine. These patients are perhaps a great deal more common than ordinarily supposed. Many of the difficulties mentioned by Dr. Plotz may be obviated by the introduction of insulin protamine, which he has mentioned. My experience with this form of insulin has been limited, but I am certain from that limited experience that patients react differently to insulin protamine, just as they react differently to ordinary insulin. The divergence is not nearly so great, but at the same time it will be necessary to individualize the slow acting insulin the same as we do with the insulin we are employing today.

DR. RUSSELL M. WILDER, Rochester, Minn. An effective way of handling many patients is to give a dose of insulin without food late in the evening. Some very severe cases can be handled with two injections in this manner, one dose before breakfast and the second dose at 8 or 9 o'clock in the evening. It is not true, as at first was taught, that every dose of insulin must immediately be buffered by food. That depends on the height of the blood sugar level and the time of day at which the insulin is given, and if a patient misses a dose or forgets to take a dose of insulin before a meal, there is no objection, and indeed it is highly important, that he should take the dose immediately after the meal. Mild cases of diabetes and moderate cases never have been very difficult to manage, but all of us have had experience with so-called brittle cases with high blood sugars at one time and reaction to insulin, with a rapid falling of blood sugar and the development of symptoms of insulin shock at other times of the day. It is not unlikely that the insulin of eight or ten years ago was slower in its action than the highly purified water soluble insulin with which the manufacturers recently have been supplying us. We saw fewer cases of this brittle type before than we do now. The insulin as it is supplied to us at the present time is as pure as granulated sugar. It is rapidly absorbed and its effect thus is more explosive. The insulin of a few years ago possibly contained zinc, perhaps other metals, as contaminants, and these metals delayed its action. This perhaps is the explanation of why we are having so much more trouble now than we used to have. Dr. Plotz mentioned insulin protamine and other longer acting insulins that recently have been introduced. I hope that those who haven't been able to see them may come to the diabetes exhibit and study some of the charts that are there of patients who have received insulin protamine. We have been experimenting with different types of diets and different types of administration of this new drug and are very much pleased to find that our best results occur when a single dose of the insulin protamine is given before breakfast in the morning. This of course, is most convenient for the patient. We have demonstrated clearly that in the average case the action of insulin protamine extends into the second and third day, as a cumulative effect. This adds to the difficulty of judging the dose but permits administration of insulin at whatever time of the day is most convenient. The advantages in insulin protamine and other longer acting insulins are first this matter of convenience, second a continuous insulin action over the twenty-four hours. The duration of action of regular insulin is not over six hours. Unless one gives four injections a day there must be periods when the patient is not receiving any help. Such periods probably are dangerous, at least they are harmful. The use of insulin protamine overcomes this difficulty.

Milk and Vitamins—Milk contains all the known vitamins. While each of the vitamins may be found in other foods also and some of them often in higher concentrations there are few if any other foods which furnish all these vitamins in such well balanced proportions as does milk.—Sherman H. C. Food and Health, New York, Macmillan Company 1934.

⁴ Greene, C. H. Personal communication to the author.

ALCOHOL INJECTION IN THE TREATMENT OF MAJOR TRIGEMINAL NEURALGIA

FRANCIS C GRANT M D
PHILADELPHIA

Clinically the diagnosis of major trigeminal neuralgia is not difficult. A vicious lancinating paroxysmal pain in either side of the face referred to the tongue or teeth, the upper or lower lip, nose or forehead in man or woman of 50 or 60 especially if a characteristic burst of pain can be excited by slight irritation of a particular point on the tongue lips or cheek, constitutes briefly the syndrome called *tic douloureux*. Relief from this dreadful pain can be afforded only by blocking the sensory pathways in the trigeminal nerve either peripheral to the gasserian ganglion or between the ganglion and the brain stem.

Surgical measures to sever the sensory root of the fifth nerve have been repeatedly described and standardized, but the value of peripheral block with alcohol of the appropriate branch of the trigeminal nerve as a means for relieving the pain of *tic douloureux* and as an aid in the differential diagnosis of this condition has received less attention.

In this country the extra-oral subzygomatic technic described by Levy and Baudouin¹ is most commonly used in the injection of the mandibular and maxillary branches of the fifth nerve. The intra-oral method devised by Schlösser² and advocated by Ostwald,³ as well as the maneuvers necessary to inject the gasserian ganglion itself described by Hartel⁴ and so strongly advised by Harris,⁵ have met less favor. Patrick⁶ in 1907 and again in 1912 reported satisfactory results with the Levy-Baudouin method and did much to popularize it. In 1922 I⁷ published two reports describing certain refinements making for greater accuracy in performing the injection by this technic and hence more satisfactory clinical results. Horrax and Poppen⁸ in 1935 reported a large series of successful injections employing the extra-oral subzygomatic approach.

Any description of the technic used in injecting the maxillary or mandibular branches of the trigeminal suggests that they can be reached with ease and accuracy. But these nerves are roughly 3 mm in diameter and lie from 4.5 to 5.5 cm beneath the skin. Complete relief of pain demands that the alcohol be injected directly into the nerve sheath. Certain fixed external landmarks exist and fairly precise instructions can be given for the direction and depth of the injecting

needle. But these external landmarks will have slightly different relationships to the deeper structures in brachycephalic or dolichocephalic individuals. Hence the practice of this technic on the cadaver prior to its clinical application cannot be too strongly urged.

The armamentarium necessary for alcohol injection consists of two hypodermic needles 1.5 and 3 cm in length with two 2.5 cm syringes and two 22 gage lumbar puncture needles. The bevel of these needles should be shortened by polishing to a 22.5 degree angle. If the bevel is long as in the standard needle, the point alone may be in the nerve sheath. Hence alcohol can leak out through the heel of the bevel and not enter the nerve. A protractor for measuring angles with a centimeter scale on its base and small bits of cork to act as stops to fit on the shafts of the needles and thus determine the depth of penetration together with 10 cc of 2 per cent procaine hydrochloride and 5 cc of absolute alcohol complete the necessary equipment.

The patient is placed on the back with the head elevated on a sand pillow and turned to expose the cheek area through which the injection is to be made. Local anesthesia is always used and never injected deeper than the zygoma. If the deeper structures as well are

infiltrated with procaine it may be difficult to determine whether resulting anesthesia is due to procaine having reached the nerve or to alcohol. A general anesthetic is unsatisfactory because the pain reaction caused by the entrance of the needle point into the nerve is the only definite evidence that the needle has been properly placed. When the patient complains of pain in the upper or lower lip, a drop or two of alcohol is injected. The area is then tested for anesthesia and, if loss of pain sensation can be demonstrated, 0.75 cc of absolute alcohol is injected. Complete anesthesia should be produced. If the needle point is properly engaged in the nerve some force will be required to introduce the alcohol.

TECHNIC

Injection of the Supra-Orbital Nerve—This nerve is injected as it emerges from the supra-orbital foramen. The supra-orbital notch is easily palpated in the orbital ridge. A hypodermic needle is inserted through the skin directly into the foramen. The plane of this foramen is usually at an angle with the midline from without inward. The needle on engaging the foramen in the ridge may be directed slightly outward to enter the canal itself. Care must be taken to hug the bone closely with the needle tip to avoid infiltration of alcohol into the orbit. When the needle enters the nerve pain

will radiate over the forehead toward the hairline and down the bridge of the nose. The nasal branch is often difficult to block, for it may divide from the main trunk of the supra-orbital well within the bony canal.

Injection of the Maxillary or Second Division—The landmarks for this injection are the external auditory canal and the lower border of the zygoma, which is

mark the needle is introduced inward forward and upward at an angle of 115 degrees with the skin surface from above downward and from before backward. The needle passes upward and forward in the plane of the external canthus of the eye but is directed behind the eye as though it were pointed at the optic nerve. At a depth of about 5 cm bone will be encountered; the pterygoid plate of the sphenoid. The outer end of the needle must now be slightly depressed so that the point will pass in front of this obstruction and enter the pterygopalatine fossa. Without change in direction the needle is now advanced from 0.5 to 0.75 cm farther and should encounter the nerve. When the nerve is touched the patient will instantly complain of severe pain in the upper lip and the ala of the nose; 0.75 cm of alcohol can now be injected.

The only hazard connected with injection of the maxillary division is too deep penetration of the needle; 6.5 cm is the maximum depth compatible with safety, although in a long narrow skull this penetration might result in puncture of the nose or orbit. The orbital structures should, of course, be most carefully avoided. Paresis of the external rectus muscle and diplopia have followed too deep an injection. Fortunately, this muscle paralysis is usually only temporary.

In a certain percentage of cases, as has been shown, the pterygoid wing may extend so far upward and forward and the pterygopalatine fossa be so deep that the nerve cannot be reached by this approach. Some of

TABLE 5—Complications Following Injections

the unsuccessful attempts to inject the maxillary nerve are due to these abnormalities in the anatomy of the structures that surround it.

Injection of the Mandibular Nerve—The anterior edge of the bony wall of the external auditory meatus and the lower edge of the zygoma again form the external landmarks. The mandibular notch of the jaw is palpated through the skin. A point 2 cm in front of the anterior edge of the external auditory canal will center on the mandibular notch. The needle is inserted at this point and directed inward at right angles with the skin in the horizontal plane and slightly upward at

Fig. 2—Same patient showing angle of needle from before backward.

an angle of 110 degrees from above downward in the vertical plane. At a depth of $3\frac{1}{3}$ to 4 cm bone is encountered and by lowering the point of the needle 1 or 2 mm one advances it another 0.5 cm to encounter the nerve. As the needle point engages the nerve the patient will complain of pain in the lower lip and tongue. No anatomic obstacle prevents injection of the mandibular nerve by this route. In about 25 per cent of cases the plane of the foramen ovale contains

ward sufficiently from the midline for the needle point to enter it. Hence the injection of the ganglion may be made if indicated. If the needle point is dropped too low and the penetration is too deep, the nasopharynx is entered. More frequently the needle is directed too far posteriorly and the eustachian tube encountered, causing pain in the ear. If this occurs the needle should be withdrawn a centimeter or two and directed slightly more anteriorly. The chief reason for lack of success in reaching the mandibular nerve is too deep insertion of the needle as the result of introducing it too low and encountering bone behind the location of the nerve.

This report is based on a series of 331 injections of the various branches of the trigeminal nerve. Two hundred and fifty injections were given to 185 patients suffering from major trigeminal neuralgia. Eighty-one injections were performed on sixty-nine patients suffering from pain in the trigeminal area due to malignant disease of the lips, tongue, cheek, nose or maxillary sinus. The tables show the age incidence, sex, laterality, branch of the trigeminal injected, percentage of successful injections and average period of relief from pain. The statistics in the cases in which injection was done for malignant conditions are included only in the last two groups. Lastly the rare complications are recorded.

Alcohol injection of the peripheral branches of the trigeminal nerve by the technic described is a valuable procedure. By its use a positive diagnosis of major trigeminal neuralgia can be reached. If a patient has pain in the face and if the branch of the trigeminal nerve supplying the skin area to which the pain is referred is successfully blocked, producing anesthesia and relief of pain, this is definite proof that the pain traveled over sensory pathways in the fifth nerve. But if the expected anesthesia is produced and the pain is not relieved, the case is one of the vague group described by Cushing⁹ and by Glaser¹⁰ as atypical facial neuralgia and further procedures directed against the fifth nerve are useless. Many an unnecessary section of the sensory root of the trigeminal could have been avoided if this test had first been applied.

Early sufferers from *tic douloureux* shy away from an immediate operation and demand nonoperative relief. Alcohol injection will afford this for more than a year at least. Furthermore, the patients become accustomed to the anesthetic area on the face and when they return for operation are completely satisfied to learn that a subtotal avulsion of the sensory root will not markedly increase this anesthesia while permanently relieving the pain.

In eleven cases in this series the patients presented themselves for operation but were so starved and dehydrated on account of the pain caused by eating or drinking that a preoperative nerve block was necessary. With the pain relieved, proper water intake and nourishment could be given to make them fit subjects for operation. Fourteen patients were over 75, two over 90. Relief of pain by alcohol injection was obviously much to be preferred to operation.

With regard to the cancer cases little need be said. Attention has been drawn previously to the value of blocking appropriate nerves to relieve the continuous and distressing pain only too often accompanying

malignant disease of the face.¹¹ This seems a simple act of mercy all too infrequently employed. Not only is the pain stopped but radical treatment no longer causes suffering. And occasionally the ability to sleep, eat and accept intensive treatment without pain has rallied these people to the point at which complete disappearance of the malignant tumor has occurred.

The disadvantages of alcohol injection briefly are that it is a painful procedure, that even in experienced hands the nerve may not be successfully blocked, and that occasionally a temporary external rectus or facial palsy may result.

3400 Spruce Street.

ABSTRACT OF DISCUSSION

DR. WALTER E. DANDY, Baltimore. My reaction to Dr. Grant's paper is one of surprise. How could such a good surgeon perform so many alcoholic injections? The operative attack is so safe and the result is permanent. I do not like alcoholic injections. There are, of course, some indications for them but these are not frequent. Occasionally one may have difficulty in making a differential diagnosis between glossopharyngeal neuralgia and trigeminal neuralgia, or between trigeminal neuralgia and one of the obscure pains in the face, but such uncertainties are uncommon. Then, too, in malignancy or in a very senile patient whose tenure of life is quite brief alcoholic injections may be in order but for the ordinary patient with trigeminal neuralgia, I cannot believe that there is any indication. Injections are very painful at best, and patients who have had one are very reluctant to endure another, especially when relief is only temporary. A patient with trigeminal neuralgia must look forward to repeated injections every year or year and a half until the end of life. Usually the pain of the injection is such a terrible ordeal that they are even willing to suffer the pain for some time before again consenting to another injection. My feeling is that as soon as the diagnosis is made, the only form of treatment is section of the sensory root of the fifth nerve either partially or totally, as the case demands. I usually put the situation before a patient telling him that he can have the alcoholic injection with temporary relief or have the operation which will take practically no risk now in safe hands and it is very uncommon indeed, for anybody to choose the alcoholic injection.

DR. J. GRAFTON LOVE, Rochester, Minn. I will present the results of the experiences I have had at the Mayo Clinic with the use of alcohol injection in major trigeminal neuralgia. We have had practically no experience with the use of alcohol in the malignant conditions about the face. At the clinic we ordinarily recommend from one to three deep injections of alcohol before advising operation or accepting the patient's request for operation. As Dr. Grant stated the injection of alcohol serves to clinch the diagnosis. It educates the patient to the feeling of absolute numbness which it gives him in lieu of the pain. In decrepit patients or patients with far advanced heart or kidney disease the operation is contraindicated. The latter indication for alcohol injection, however, is met less and less frequently, for we have recently completed a series of more than 300 operations on the trigeminal nerve by the trans-temporal approach, without a death. Alcohol injection is recommended for patients who have had trigeminal neuralgia for only a short time, for patients in whose history there is some doubt as to the true diagnosis of the condition and for patients in whom an operation even of this mild risk, is contraindicated. All patients suspected of having trigeminal neuralgia are seen by a neurosurgeon in consultation with a member of the neurologic department. The neurosurgeon recommends the type of treatment to be carried out. If alcohol injection is decided on the patient is referred to the department of oral and plastic surgery. These surgeons devote all their time to diagnosis and treatment of conditions about the face. They have been doing alcohol injections for years. The injections are given under gas anesthesia so that the patient experiences no pain. I too have had the experience of recom-

mending alcohol injection to a patient who has had a previous injection and having it flatly refused. The patient said he would rather keep the pain than be subjected to the injection under a local anesthetic. I think that has been the experience of most people. After one or, at most, three injections of alcohol, we advise or meet the patient's request for a division of the sensory root. We carry out the transtemporal operation, subtotal section of Frazier or the complete section of the sensory root between the ganglion and the pons.

DR. PETER BASSOE, Chicago. With the great improvement in the radical surgical treatment of trifacial neuralgia, I now feel it my duty to try to persuade the victims to have operation rather than alcohol injection. Still some patients prefer the injection treatment. I note with interest that Dr. Grant uses a different landmark for the deep injection of the middle branch than the one recommended by Levy and Baudouin. I have found the latter landmark satisfactory and have had more difficulty with the lower branch. As to the use of injection in differentiating between trifacial and glossopharyngeal neuralgia, I have had a peculiar experience. I have seen only five or six cases of glossopharyngeal neuralgia, and two of them were complicated by trifacial neuralgia. I have found that injection can be made fairly painless by first injecting procaine and epinephrine. I congratulate Dr. Grant on having paralyzed only the sixth nerve, as I have also paralyzed the third nerve several times. Fortunately this paralysis soon disappeared.

DR. ERNEST SACHS, St. Louis. I have seen many cases of pain in the face in which I was unable to make a positive diagnosis of trigeminal neuralgia. Possibly because I am in St. Louis I see many cases of the late Dr. Sluder in which differential diagnosis is extremely difficult. In those cases, as Dr. Grant has said, I think it is invaluable to try the alcohol injection first to establish the diagnosis. Then there is also a limited number of cases as he said in which the pain has existed for a very brief time. In those cases I think the alcohol injection first is of distinct value.

DR. JAMES RUDOLPH JAEGER, Denver. I have had the experience in a number of instances of having produced a complete anesthesia over the particular division of the fifth cranial nerve. I have injected and then finding that the neuralgia persisted over that division. In other words, I do not think that a satisfactory area of anesthesia with pain still referred to that area is always positive evidence that the pain is not that of tic douloureux. If one gets anesthesia and still has the pain typical of tic douloureux in the anesthetic area, it certainly leads one to believe that the pain exists in the ganglion itself or at least in the root of the fifth nerve between the ganglion and its foramen of exit from the skull. In a number of cases in which I produced good anesthesia over the root of the fifth nerve by alcohol injection subsequent section of the sensory root cured the neuralgia. I do not think that alcohol block in the peripheral branch is always of diagnostic value in true major trifacial nerve pain. As Dr. Grant has said, most neurosurgeons prefer not to inject the ganglion. They are fearful of this procedure. It is my belief that the person who does a good complete ganglion injection with alcohol must be a very brave person. As yet I have not developed the courage to do the ganglion injection.

DR. A. L. SKOOG, Kansas City, Mo. I am wondering if Dr. Grant has had experience with cases that seem to have been restored by injection of the branches. Some fifteen years ago Dr. Adson of the Mayo Clinic referred to me a patient for repeated injections. She was an elderly woman with advanced arteriosclerosis, hypertension and a bad heart. She was not considered a good risk for operation. She had a blood pressure of 270 systolic on several occasions. The second and third branches of the right side were involved. I made six or seven injections in the course of two years. Then she went on requiring no injections, apparently free from pain for some time like five years and died. Unfortunately we had no autopsy. She was 77 or 78 at the time of her death. Possibly enough alcohol had been injected on several occasions to produce a sclerosis and more or less complete blocking of pain.

DR. GRANT, Philadelphia. Alcohol injection has a definite place in the treatment of trigeminal neuralgia. Certain patients refuse operation; in others the diagnosis between
